Another study investigated whether dietary olive oil consumption over time affected the incidence of hypertension (Alonso & Martinez-Gonzalez 2004). Data from 6863 participants with at least 2-year follow-up was used and the study found that olive oil consumption was associated with a reduced risk of hypertension among men; no association was observed among women. The researchers suggested this might be attributed to the overall lower incidence of hypertension among females and the resulting lower statistical power. A recent study, of 772 participants, using the Mediterranean diet confirmed that dietary olive oil reduced SBP by 5.9 mmHg (Estruch et al 2006).

Olive leaf

A study of olive leaf extract involving 30 subjects with essential hypertension was conducted by the Service de Cardiologie, Hospital Militaire in Tunis (Cherif et al 1996). Olive leaf extract (1600 mg/day) was administered for 3 months, after 15 days treatment with a placebo. Active treatment resulted in a statistically significant decrease in blood pressure ($P < 0.001$) in all patients and was considered well tolerated. Other interesting observations were that patients previously treated with beta-blockers noted a disappearance

of gastric symptoms during treatment with olive leaf extract. Another olive leaf extract (EFLA943) in an open study, with 40 borderline hypertensive twins, showed that treatment with 1000 mg/d of this supplement significantly decreased blood pressure and lowered cholesterol levels (Perrinjaquet-Moccetti et al 2008).

Inflammatory conditions

Olive leaf extract is used to promote symptomatic relief in various inflammatory conditions, such as osteoarthritis and asthma, and as a gargle in tonsillitis and pharyngitis. The anti-inflammatory effects demonstrated by several major components in olive leaf provide a theoretical basis for its use; however, clinical trials are not yet available to determine whether effects are significant and efficacy remains speculative.

Alternately, olive oil supplementation has been tested in some clinical studies.

Rheumatoid arthritis

In some studies of RA in which fish oil supplements have been investigated, olive oil has been used as a placebo because it was generally regarded as containing neutral fatty acids; however, in some instances olive oil produced significant improvements in disease activity, prompting further research.

Supplementation for 12 weeks with olive oil resulted in a significant decrease in pain intensity, duration of morning stiffness, time taken to walk 18 m, and fibrinogen levels and improved trends in erythrocyte sedimentation rate, C3, and right grip strength according to an early study (Darlington & Ramsey 1987). A later double-blind study found subjective measures of mean duration of morning stiffness and analogue pain score improved to the same extent as treatment with fish oil supplements after 12 weeks (Cleland et al 1988).

A 24-week double-blind, randomised study of two different dosages of fish oil (3 g/day and 6 g/day) and a single dosage of olive oil (6.8 g/day of oleic acid) was conducted with 49 subjects with active RA (Kremer et al 1990). The fish oil treatment produced better results overall; however, improvement in patients' global assessment was only observed with olive oil supplementation.

Another double-blind study of 90 patients comparing treatment with fish oils (2.6 g/day), or fish oils and olive oil (1.3 g/day and 3 g/day, respectively) or olive oil (6 g/day) over 12 months found a significant decrease in Ritchie's articular index of pain and the number of painful joints after 12 months of olive oil and also after the combined use of fish oil (1.3 g/day) and olive oil (3 g/day) (Geusens et al 1994).

More recently, a study of 43 patients investigated the effects of placebo (soy oil), fish oil (3 g/day), and a combination of fish oil (3 g/day) and 9.6 mL/day of olive oil as an adjunct to standard treatment (Berbert et al 2005). The groups receiving fish oil and the fish oil/olive oil combination experienced a statistically significant improvement in joint pain intensity, hand grip strength, duration of morning stiffness and onset of fatigue compared with placebo. Parameters that responded after 24 weeks were Ritchie's articular index for joint pains, the ability to bend down to pick up clothing from the floor and getting in and out of a car. The group using the fish oil/olive oil combination also experienced improved ability to turn taps on and off and decreased rheumatoid factor after 24 weeks. When groups were compared, the combination treatment was found to be superior, showing a significant improvement in patient global assessment after 12 weeks.

A recent randomised, double-blind, placebo-controlled trial of 90 subjects with RA or osteoarthritis found that treatment for 8 weeks with an olive extract (freeze-dried olive vegetation water at a dose of 400 mg/day) significantly reduced pain and daily living improvements compared with a placebo (Bitler et al 2007).

Cancer prevention

It has been speculated that consumption of olive oil, chiefly as an ingredient of the Mediterranean diet, may reduce the incidence of some cancers, based on the observation that the incidence of cancer overall in Mediterranean countries is lower than in Scandinavian countries, the United Kingdom and the United States (Trichopoulou et al 2000, Visioli et al 2004).

One review calculated that up to 25% of the incidence of colorectal cancer, approximately 15% of the incidence of breast cancer and approximately 10% of the incidence of prostate, pancreas and endometrial cancers could be prevented if the populations of highly developed Western countries shifted to the traditional healthy Mediterranean diet (Trichopoulou et al 2000). Although these figures are only estimates, data from observational studies is now considered strong enough to suggest that the traditional Mediterranean diet should be actively promoted in order to reduce the incidence of cancer (Visioli et al 2004). This finding was confirmed with the National Institutes of Health (NIH) prospective US study which found that the Mediterranean diet was associated with reduced deaths due to both cancer and CVD (Mitrou et al 2007).

Olive oil was shown to be significantly protective of breast cancer in a population-based study in the Spanish Canary Islands with a total of 755 women who completed a food frequency questionnaire (García-Segovia 2006). Another study looked at the influence of the Mediterranean diet on high mammographic breast density (associated with an increased risk of breast cancer). This longitudinal study assessed dietary and lifestyle information from 2000 women and found that breast density was inversely associated with olive oil consumption and was therefore a possible protective factor against breast cancer in this community (Masala et al 2006).

Diabetes

There is anecdotal evidence that people with type 2 diabetes are using olive leaf extract as an adjunct to dietary modification. One report from Morocco found that 80% of people surveyed used herbal medicines for diabetes, hypertension and cardiac disease,

and olive leaf was one of the most popular treatments (Eddouks et al 2002). A recent animal study with olive leaf extract in streptozotocin-induced diabetic rats discovered a significant reduction in various markers including a decrease in serum glucose, triglycerides and total cholesterol. Compared with the diabetic drug glibenclamide, the olive leaf was more effective (Eidi et al 2008). The significant hypoglycaemic activity reported in animal models provides a theoretical basis for its use; however, clinical testing is not yet available to determine whether effects are significant and efficacy remains speculative.

Longevity

In 2002, Panagiotakos et al found that adherence to a Mediterranean diet and healthy lifestyle (non-smoking, physically active and moderate drinking) is associated with a greater than 50% lower rate of all-cause and cause-specific mortality, such as from coronary heart disease, cardiovascular diseases and cancer (Knoops et al 2004). The cohort study involved 1507 apparently healthy men and 832 women, aged 70–90 years in 11 European countries and was conducted from 1988 until 2000.

A year later, Trichopoulou et al (2003) also reported a positive association between longevity and the Mediterranean diet, with their study showing that the benefits are significant in people aged 55 years and older.

More recently, a 2004 review of five cohort studies further confirmed these findings and concluded that there is now sufficient evidence to show that diet does indeed influence longevity and that the optimal diet for the prevention of both coronary heart disease and cancer is likely to extensively overlap with the traditional Mediterranean diet (Trichopoulou & Critselis 2004). Although it is uncertain which specific components in the Mediterranean diet are most important for its protective health benefits, olive oil, fish, plant foods and moderate wine consumption are likely candidates.

Antibacterial, antifungal and antiviral

Based on evidence of its broad-spectrum antimicrobial activity, olive leaf extract is used for the treatment of common bacterial infections such as bronchitis and tonsillitis, common fungal infections such as vaginal candidiasis, *Tinea pedis* and *Tinea capitis*, and viral infections such as herpes simplex. The in vitro antifungal activity of olive and olive oil may be useful in the topical treatment of fungal infections (Battinelli et al 2006). Currently, controlled studies are not available to determine whether treatment is effective.

OTHER USES

Olive oil is an emollient and used externally to relieve pruritis and inflamed surfaces and is used to soften and remove dry scales in eczema and psoriasis. Topically oleuropein may have potential to protect and to repair after UV damage (Perugini et al 2008). Taken internally, it is used as a laxative to soften impacted faeces. As a folk remedy, the plant is used as a diuretic, hypotensive, emollient, febrifuge and tonic, for urinary and bladder infections and for headaches (Somova et al 2003). Olive leaf extract is also used as a general tonic to improve energy and provide a sense of wellbeing.

DOSAGE RANGE

General recommendations

- Olive leaf extract (according to manufacturer's recommendations): 5 mL three times daily diluted with water or juice if necessary (Olive Leaf Australia 2006).
- Olive oil: should replace dietary intake of saturated fats and be consumed as part of a Mediterranean-style diet.

According to clinical studies

- Hypertension: 1600 mg/d of olive leaf extract or 50 mL/day of virgin olive oil.
- Rheumatoid arthritis: 6–10 g/day of olive oil long term.
- Breast cancer: highest protective effects at 30.5 g/day.
- Cardiovascular protection: 25 m–50 mL/day of virgin olive oil.

ADVERSE REACTIONS

Allergenic pollen is produced by the Oleaceae family, including the olive tree, which causes seasonal respiratory allergies in Mediterranean countries.

SIGNIFICANT INTERACTIONS

Controlled studies are not available, so interactions are theoretical and based on evidence of pharmacological activity with uncertain clinical significance.

Hypoglycaemic agents

Theoretically, an additive hypoglycaemic effect is possible but is speculative — possible beneficial interaction under professional supervision.

Hypertensive agents

Theoretically, an additive hypotensive effect is possible but is speculative — possible beneficial interaction under professional supervision.

CONTRAINDICATIONS AND PRECAUTIONS

People with known allergies to the Oleaceae family of plants should avoid this herb.

PREGNANCY USE

Olive oil is likely to be safe when consumed in dietary amounts; however, the safety of olive leaf extract is not known.

PATIENTS' FAQs

What will this herb do for me?

Long-term consumption of olive oil as part of a Mediterranean diet is likely to reduce the incidence of heart disease and promote longevity. It may also reduce the risk of cancer; however, this is less well established. Used as a stand-alone supplement, it may reduce blood pressure and improve symptoms in rheumatoid arthritis. Olive leaf extract may also be useful in hypertension and inflammatory conditions; however, little research has been conducted to confirm effectiveness.

PRACTICE POINTS/PATIENT COUNSELLING

- Consumption of olive oil has beneficial effects on arterial blood pressure and reduces the risk of cardiovascular disease when ingested as part of the Mediterranean diet.
- Several studies have demonstrated that supplemental olive oil produces significant improvements in disease activity in rheumatoid arthritis.
- When used as part of the Mediterranean diet, olive oil may reduce the incidence of some cancers and increase longevity.
- Olive leaf extract contains a greater concentration of biologically active phenolic compounds than olive oil; however, it has not been significantly studied in clinical trials.
- Preliminary studies with olive leaf extract show that it has significant anti-inflammatory and antioxidant activity and possibly hypoglycaemic effects.

When will it start to work?

In rheumatoid arthritis, benefits start to appear after 12 weeks with further improvement noticed after 24 weeks. In regards to other health benefits, olive oil should be used long term.

Are there any safety issues?

Dietary amounts of olive oil are well tolerated and considered safe in healthy individuals; however, the safety of olive leaf extract has not been well studied and it should be avoided in pregnancy until safety is established.

Extra-virgin olive oil is likely to have the greatest antioxidant effects.

Orange

HISTORICAL NOTE The root word for orange is the Arabic, *narandj* (Sellar 1992). The orange is a symbol of innocence and fertility. Some scholars believe the 'golden apple' Paris presented to Venus was actually an orange. In return, Venus bestowed Helen on Paris as a reward for selecting her in a beauty contest, which eventually caused the Trojan War. The tree is indigenous to eastern Africa, Arabia and Syria and it is believed that the crusaders may have introduced the orange to Europe when they returned from the crusades. Unripe dried fruits and the fruit peel are incorporated into various products, including foods such as marmalade, alcoholic beverages such as Curaçao and medicinal products including weight loss products. The essential oil is used in perfumes, cosmetics and aromatherapy (Leung & Foster 1996), as food flavouring and to disguise the unpleasant taste of medicines. Orange blossom water has been used for centuries in Mediterranean countries to flavour cakes and beverages (Jeannot et al 2005). Orange oil is used in various alcoholic beverages such as Grand Marnier, Curaçao, Triple Sec and Chinotto (*Citrus aurantium myrtifolia*) and in Chinese medicine (*Citrus aurantium daidai*).

COMMON NAME
Orange

OTHER NAMES
Bitter orange, *Citrus sinensis*, green orange, Seville orange, Zhi Shi

BOTANICIAL NAME/FAMILY
Citrus aurantium var. *dulcis* (sweet orange) and *Citrus aurantium* var. *amara* (bitter orange or neroli) (family Rutaceae).

PLANT PARTS USED
Fruit, dried outer peel of the ripe fruit, and essential oils and floral water (orange blossom water).

CHEMICAL COMPONENTS

Bitter orange peel
Essential oil (0.2–0.5%), monoterpenes linalyl acetate, pinene, limonene, linalool, nerol, geraniol, bitter substances, flavonoids and methyl anthranilate, the alkaloid synephrine and *N*-methyltyramine (Blumenthal et al 2000, Pellati et al 2002). Synephrine is structurally similar to adrenaline.

Essential oils

Essential oil species	Major components	Minor components
Citrus aurantium var. *dulcis*	Limonene 89%	Linalool
	Myrcene 1.7%	Neral
	Beta-bisabolene 1.29%	Geranial, neral, citronellal, sabinene, myracene
Citrus aurantium var. *amara*	*d*-limonene 89–96%	Nerol, geraniol, linalyl acetate
		Bergaptene 0.069–0.073%
		Furanocoumarins (in cold pressed but not in steam distilled oils)

(From Price and Price 1995, Sellar 1992, Verzera et al 2004.)

Clinical note — Three different essential oils

C. aurantium var. *dulcis* (sweet orange) and *C. aurantium* var. *amara* (bitter orange or neroli) are obtained from the peel and are usually expressed oils.

Neroli essential oil is obtained from the flowers of *C. aurantium* var. *amara* by steam distillation and very occasionally enfleurage and is known as Neroli Bigarade, which is said to be the best Neroli essential oil available. Neroli essential oil obtained from *C. aurantium* var. *dulcis* is known as Neroli of Portugal.

Petitgrain is obtained from the leaves of *C. aurantium* var. *amara* by steam distillation.

Each of these oils has a different chemical profile and, therefore, different uses. Distilled essential oils are used more in food flavourings and expressed essential oils in aromatherapy and perfumes because of their stronger fragrance (Tisserand & Balacs 1995). This monograph concentrates on expressed sweet orange and bitter orange essential oils.

Terpeneless/deterpenated or concentrated orange oil is sometimes available. Although the terpenes are removed, terpeneless orange oils retain all their other chemical components, including the furanocoumarins, which are in larger amounts, and this increases their phototoxic potential. Therefore, the safe concentration in blends containing terpeneless oils is less than 0.2% (Tisserand & Balacs 1995).

Methyl anthranilate is an important compound that may give orange flowers their aroma (Jeannot et al 2005).

The composition of orange essential oils is described by the International Standards Organisation (ISO) under the following standard numbers 1340: 2005:

9844: 1991	Bitter orange *C. aurantium* var. *amara*
8901: 2003	*C. aurantium* (petitgrain)
3517: 2002	*C. aurantium* var. *amara* (neroli)
4735: 2002	Oils of citrus

MAIN ACTIONS

Sympathomimetic

Considering *C. aurantium* contains biologically active adrenergic amines, it may exert sympathomimetic activity.

An in vivo study found no significant effects on blood pressure when two concentrations of *C. aurantum* tincture (standardised to 4% synephrine or 6% synephrine) were administered (Calapai et al 1999). However, analysis of myocardial electrical activity showed ECG alterations such as ventricular arrhythmias with enlarged QRS complex. The effect was present after 5 days of treatment and became significant at day 10 and was still evident after 15 days. These effects may be explained by the positive chronotropic activity of synephrine, which has been observed on isolated atria from reserpinised guinea pigs due to beta$_1$-adrenoceptor agonist activity, but could also be due to other constituents.

Appetite suppressant

Synephrine produces effects on human metabolism, which could be useful for reducing fat mass in obese humans because it stimulates lipolysis, raises metabolic rate and fat oxidation through increased thermogenesis (Pellati et al 2002). A controlled in vivo study of *C. aurantium* fruit hydro-alcoholic extracts standardised to synephrine 4% (Ci. au. 4%) and 6% (Ci. au. 6%) found that repeated administration of the extract significantly and dose-dependently reduced food intake and body weight gain (Calapai et al 1999).

Antibacterial

Seville orange has strong in vitro antibacterial activity against *Escherichia coli* and *Staphylococcus aureus* (Melendez & Capriles 2006).

Antiviral

The fruit of *C. aurantium* has a potent inhibitory activity on rotavirus infection (Kim et al 2000). The active components are neohesperidin and hesperidin.

Antifungal

Bitter orange essential oil has been shown to be effective in treating resistant fungal skin conditions (Ramadan et al 1996).

Digestive effects

The essential oil of *C. aurantium* var. *dulcis* is believed to aid digestion by stimulating the flow of gastric juice and has antispasmodic and carminative actions. The essential oil of *C. aurantium* var. *amara* is considered to be a liver stimulant, reduces gastric spasm and relieves symptoms of indigestion (Price & Price 1995, Wichtl & Bisset 1994). It is also thought to lower cholesterol.

Aromatherapy effects

The essential oil of *C. aurantium* var. *dulcis* is considered to convey warmth and happiness and improve mood (Battaglia 1997), reduce stress, aid sleep by reducing stress (Miyake et al 1991), and aid concentration. The essential oil of *Citrus aurantium* var. *amara* is considered to have a calming effect and is considered one of the most effective sedative essential oils (Battaglia 1997, Price & Price 1995, Wichtl & Bisset 1994).

OTHER ACTIONS

Antioxidant

Natural antioxidants obtained from 'citrus oils' have been shown to inhibit oxidation of LDL cholesterol in in vitro studies (Takahashi et al 2003), possibly due to the gamma-terpinene content. Terpinolene and alpha-terpinene also showed antioxidant properties. Takahashi et al suggested gamma-terpinene could be added to foods and beverages to prevent oxidation. Sellar (1992) suggested that sweet orange oil aids the absorption of vitamin C.

CYP3A4 inhibition

Bergamottin and 6′,7′-dihydroxybergamottin found in Seville oranges inactivate intestinal CYP3A4, as demonstrated clinically. Other furanocoumarins, including bergapten, could also be involved (Malhotra et al 2001).

CLINICAL USE

Heartburn and dyspeptic symptoms

The primary indication for bitter orange tincture or extract is heartburn (Blumenthal et al 2000). The dried peel is officially listed in the British Pharmacopoeia (British Herbal Medicine Association Scientific Committee 1983) as a bitter tonic and empirical evidence suggests that it acts as a carminative agent. Commission E approves the use of cut peel for loss of appetite and dyspeptic symptoms (Blumenthal et al 2000).

Weight loss

Citrus aurantium extract is growing increasingly popular as an ingredient in weight loss products, substituting for the banned ephedra in the United States. The main ingredient, synephrine, produces effects on human metabolism that could be useful for reducing fat mass in obese humans because it stimulates lipolysis, raises metabolic rate and fat oxidation through increased thermogenesis.

Currently, only two small clinical studies have been published and both suggest possible weight reduction (Preuss et al 2002); more research is required to confirm effectiveness and safety.

Superficial dermatophyte infection

The oil of bitter orange (*C. aurantium* var. *amara*) was an effective topical treatment in treatment-resistant, superficial dermatophyte infection according to a study of 60 patients (Ramadan et al 1996). Patients with tinea corporis, cruris or pedis were treated with one of three treatments based on oil of bitter orange and cure was assessed by clinical and mycological examinations. One group used a 25% emulsion of oil three times daily, the second group used 20% oil in alcohol three times daily and the third group applied pure oil once daily. Treatment

with the 25% oil emulsion was most successful and resulted in 80% of patients being cured after 1–2 weeks and 20% in 2–3 weeks. The group using the 20% oil in alcohol preparation also experienced substantial cure rates, but it took longer to achieve. Application of the undiluted oil successfully cured 33% of subjects within the first week, 60% within 1–2 weeks and 7% in 2–3 weeks. The only side effect reported was mild irritation when the undiluted oil was used.

Aromatherapy

Citrus sinensis administered in massage or via inhalation has been shown to improve mood and reduce anxiety in a range of health care settings. Lehrner et al (2000) demonstrated reduced anxiety and more positive mood compared to placebo, particularly for women, using 0.25 mL essential oil added to a diffuser in a dental waiting room (n = 72). Fitzgerald et al (2007) also showed a greater effect on mood in girls than boys in a multicultural paediatric integrative medicine clinic. Interestingly, the girls reported feeling more energetic after inhaling spearmint, whereas males felt more energetic after inhaling ginger. Overall, ginger and lavender were the least liked oils. The self-reported reductions in anxiety are supported by objective measures of autonomous function: blood pressure, respiratory and pulse rates, and skin temperature (Hongratanaworakit & Buchbauer 2007). These subjects also rated themselves as being more cheerful. Likewise Fewell et al (2007) reported sedative effects of sweet orange oil administered in a massage.

Citrus aurantium var. *dulcis*

The essential oil is used to convey warmth and happiness and improve mood (Battaglia 1997), reduce stress, and promote sleep (Miyake et al 1991). It is traditionally known as 'the oil of communication and happiness'. It is also used to improve digestion and as a carminative to relieve gastric cramping and discomfort.

Citrus aurantium var. *amara*

The essential oil is used to reduce anxiety, muscle tension and promote relaxation and best used in the bath before bedtime when treating insomnia (Battaglia 1997). It is used in cosmetics to repair broken capillaries, stimulate cell regeneration and to manage acne-prone skin.

OTHER USES

Distilled orange oil is often added to foods and beverages to enhance their flavour and to medicines to reduce the unpleasant taste.

Orange blossom water or hydrosol contains small proportions of essential oils and is used on the skin as an astringent and orally as a gastrointestinal carminative (Jeannot et al 2005). There are no terpenes in orange hydrosol, so the likelihood of causing skin irritation is significantly reduced. It is also used topically as an astringent for acne-prone skin and to calm babies and induce sleep (Bellakhdar 1997, Hmamouchi 2000).

The essential oil of *C. aurantium* var. *amara* is used as an ingredient in perfumes.

DOSAGE RANGE

Bitter orange peel products

- General dose information: 4–6 g daily of cut peel for teas or other galenical preparations used for oral administration.
- Infusion: 2 g of cut peel in 150 mL boiling water taken three times daily.
- Weight loss: bitter orange 975 mg (used with caffeine 528 mg and St John's wort 900 mg in a small double-blind study).

Essential oils

- Oral LD_{50} dose: 5 g/kg (rat).
- Dermal LD_{50} dose: >5 g/kg (rabbit) (Citrus and Allied Essences 2004).
- Oral LD_{50} dose for a 15-kg child: 83 g/kg.
- Oral LD_{50} dose for a 70-kg adult: 389 g/kg.
- Oral doses in teas and other preparations: 4–6 g/day or 2 g in 150 mL of boiled water as an infusion (American Botanical Council 1999). The inhalation LD_{50} dose has not been established.
- Topical application dose of bitter orange to skin exposed to UV rays: 1.4% of a blend. However, even when topical application is combined with inhalation, blood concentrations of *d*-limonene, a component of most citrus oils, during 20 minutes of massage is low (≤0.008 microgram/mL). It is detectable in the blood within 10 min, which represents an uptake of more than 1% of the dose administered (Fewell et al 2007).

ADVERSE REACTIONS

Skin sensitisation

Both *C. sinensis* and *C. amara* are mild skin irritants, but are considered to be low risk. Skin reactions are more likely if undiluted oils are applied directly to the skin or when used on broken or inflamed skin or when other skin pathology is present. Skin reactions are idiosyncratic and can be difficult to predict. Skin sensitisation with topically applied orange oil is largely due to the components citral and cinnamic acid and is dose dependent (Tisserand & Balacs 1995) and *d*-limonene and often occurs after long-term exposure (Verzera et al 2004).

Photosensitisation

Expressed *C. sinensis* essential oil is not normally phototoxic (Tisserand & Balacs 1995), whereas *C. amara* oil is moderately phototoxic due to its furanocoumarin content, although the risk is considered low unless higher than recommended concentrations are used or more than one potentially phototoxic oil is combined in a blend. The risk may be increased in fair-skinned individuals. Other phototoxic essential oils include *Citrus bergamia* (bergamot) and *Citrus limon* (lemon). Sensitivity to sunlight or UVB light after topical application increases in the first hour after application and declines over the following 8 h. A general caution is to avoid UV exposure for at least 12 h after topical application and use a sunscreen during this period. An early study (Zaynoun 1977) (n = 63) showed no significant differences in phototoxic reactions to

bergamot oil for eye colour, age, gender or tanning, but smaller amounts of oil produced an effect in light-skinned people. It is not clear whether this also applies to orange essential oil.

Gastrointestinal symptoms

Abdominal pain, nausea, vomiting, diarrhoea and dizziness have been reported with oral dosing (Citrus and Allied Essences 2004).

Cardiotoxicity

Bitter orange, standardised to 4–6% synephrine, demonstrated cardiovascular toxicity (ventricular arrhythmias with enlargement of QRS complex) and mortality in rats (Calapai et al 1999). The clinical significance of this finding remains unknown.

SIGNIFICANT INTERACTIONS

There are no known interactions between the essential oils and conventional medicines; however, interactions may occur with the fruit and fruit products.

Theoretically, an interaction exists for CYP 3A and P-gp substrates, as human studies indicate that the juice made from *C. aurantium* (Seville orange) inhibits CYP3A and possibly P-glycoprotein (Di Marco et al 2002, Malhotra et al 2001) — use with caution.

CONTRAINDICATIONS AND PRECAUTIONS

Do not apply essential oils to eyes or undiluted to mucous membranes. Orange essential oil is flammable and should not be vaporised near sources of heat or open flames. Therefore, candle vaporisers are not recommended. Skin sensitisation and phototoxicity are possible with the essential oils, so exposure to UV light sources should be avoided for at least 12 hours after dermal application. The risk is increased in fair-skinned individuals and when a blend that also contains other phototoxic essential oils is used.

PREGNANCY USE

Bitter orange peel and associated products are not recommended for use in pregnancy (Blumenthal et al 2000).

Orange essential oil used in recommended doses is generally safe in pregnancy, but general safety precautions apply.

PATIENTS' FAQs

What will this herb do for me?

Orange essential oil can be used in a vaporiser or massage to aid focus and concentration and facilitate communication. Neroli oil is mostly used to reduce stress and promote sleep and relaxation. In teas and tinctures, cut peel may aid digestion and relieve dyspeptic symptoms. There is some evidence that the oil may be an effective treatment for treatment-resistant fungal skin infections.

When will it start to work?

When used in aromatherapy, it usually acts soon after inhalation. When the oil or oil products are applied topically to fungal infections, results may be seen within 1–2 weeks; however, 3–4 weeks of treatment may be required. Used internally, bitter orange peel products should provide dyspeptic symptom relief quickly. Used in the bath before bedtime to promote sleep, neroli oil should produce relaxing effects within half an hour.

Are there any safety issues?

Skin irritation and phototoxicity (chemical burn) are possible after topical application of the oil if the skin is exposed to UV light such as sunlight. Use in recommended doses and do not use more than 15% of orange essential oil in a blend. Oral use of bitter orange peel products is not recommended in pregnancy and Seville orange juice can induce multiple drug interactions.

PRACTICE POINTS/PATIENT COUNSELLING

- Bitter orange peel and associated products are used to improve digestion, relieve dyspeptic symptoms and improve appetite.
- *Citrus aurantium* extract is growing increasingly popular as an ingredient in weight loss products; however, controlled studies are required to determine its safety and effectiveness.
- The oil of bitter orange (*Citrus aurantium* var. *amara*) was an effective topical treatment in treatment-resistant, superficial dermatophyte infection according to one study.
- Topical application of orange oil and bitter orange oil can induce skin sensitisation, which is more likely to occur if old orange essential oil is used because of its tendency to oxidise. Appropriate storage reduces oxidation. A patch test is recommended for atopic people or those who have a tendency to skin reactions to fragrance compounds, cosmetics or essential oils.
- Topical application of orange oil and bitter orange oil can induce photosensitivity in some individuals. After topical application, exposure to sunlight or UVB light should be avoided for at least 12 h. The risk of phototoxicity increases if high concentrations of phototoxic essential oils are used or a blend contains several phototoxic essential oils or if used by fair-skinned people.

Passionflower

HISTORICAL NOTE Legend has it that this herb received its name because the corona resembles the crown of thorns worn by Christ during the crucifixion. A popular sedative medicine in the early 20th century, it was listed in the United States National Formulary until 1936.

COMMON NAME
Passionflower

OTHER NAMES
Apricot vine, granadilla, Jamaican honeysuckle, Maypop passion flower, passion vine, water lemon

BOTANICAL NAME/FAMILY
Passiflora incarnata (family Passifloraceae)

PLANT PARTS USED
Aerial parts, particularly leaves

CHEMICAL COMPONENTS
Flavonoids and related compounds (including apigenin, quercetin, kaempferol and chrysin), maltol, coumarin derivatives, indole alkaloids (mainly harman, harmaline, harmine), phytosterols (stigmasterol), sugars and small amounts of essential oil.

Harman
Numerous in vitro and in vivo trials have been conducted on the constituent known as harman. Some of these studies have suggested:
- mild monoamine oxidase A inhibition (Adell et al 1996)
- inhibition of HIV replication (Ishida et al 2001)
- vasorelaxant activity (Shi et al 2000)
- effects on GABA release (Dolzhenko & Komissarov 1984).

Harman is not considered to be one of the main active constituents in the herb and is not present in biologically active concentrations in the dosage range used for passionflower. As such, results obtained using isolated harman in vitro and in vivo cannot necessarily be extrapolated to the use of passionflower in humans.

Harman has also been identified in beer, and to a lesser extent in wine, both of which contain levels far in excess of those found in passionflower at therapeutic doses.

MAIN ACTIONS

Anxiolytic and sedative activity
Several in vivo studies have demonstrated the anxiolytic effects of Passiflora extract (Brown et al 2007, Della Loggia et al 1981, Dhawan et al 2001, Soulimani et al 1997). Behavioural tests in mice have also demonstrated that high doses have a sedative effect (Soulimani et al 1997).

The mechanism of action is currently unclear, as some research suggests stimulation of GABA release or an interaction with GABA receptors, and other research observes no interaction with GABA-benzodiazepine receptors (Zanoli et al 2000). One in vitro study also showed inhibition of GABA-A binding with Passiflora extract (Simmen et al 1999). An extract of the isolated flavone chrysin (2 mg/kg) was found to produce an anxiolytic effect similar to

midazolam, but the effect was observed to a lesser degree in vivo (Brown et al 2007).

Anticonvulsant

A hydro-alcoholic extract of Passiflora (Pasipay 0.4 mg/kg) has demonstrated anticonvulsant activity in vivo (Nassiri-Asl et al 2007). The extract was shown to delay onset and decrease the duration of seizures compared to placebo. It appeared to work through GABAergic and opioid pathways, however more research is needed to confirm the mechanism.

CLINICAL USE

Anxiety and nervous restlessness

Passiflora extract is a popular herb for nervousness and is most often prescribed in combination with other herbs such as valerian. A recent Cochrane review of two RCTs concluded that despite some positive findings, more trials with larger numbers of participants were needed to confirm efficacy in anxiety (Miyasaka et al 2007). One of the reviewed trials was a double-blind, randomised controlled study involving 36 outpatients diagnosed with generalised anxiety disorder (GAD). Passiflora extract was found to be as effective as oxazepam 30 mg/day over a 4-week period and better tolerated (Akhondzadeh et al 2001a).

Since then, a study published in 2008 produced encouraging results. Sixty patients were randomised to two groups and given passionflower (500 mg) or placebo 90 min before surgery (Movafegh et al 2008). Anxiety scores were significantly lower in the Passiflora group compared to the placebo group, whilst other parameters such as psychological and physiological recovery were the same for both groups.

Commission E approved passionflower for this indication (Blumenthal et al 2000).

Insomnia

Currently, in vivo evidence supports the sedative activity of Passiflora when used in high doses; however, controlled studies are not available to confirm the clinical efficacy (Soulimani et al 1997).

Cannabis, alcohol and opiate withdrawal

A randomised double-blind study involving 65 subjects with opiate addiction compared the effects of clonidine and placebo with clonidine and Passiflora extract over a 14-day period. The combination treatment of clonidine and Passiflora extract showed significant superiority for alleviating the psychological symptoms associated with withdrawal; however, no differences in physical symptoms were seen (Akhondzadeh et al 2001b).

Although no clinical studies are available for Passiflora extract, preliminary results from animal studies testing the benzoflavone moiety isolated from Passiflora has found it to be a useful adjunct during cannabis and alcohol withdrawal, reducing dependence and attenuating withdrawal symptoms (Dhawan et al 2002b, c).

OTHER USES

Traditional uses

Traditionally, passionflower has been used to treat neuralgia, generalised seizures, hysteria and insomnia. It has also been used to treat diarrhoea, dysentery and dysmenorrhoea by acting on the nervous system.

Aphrodisiac

Recent tests in mice have identified significant aphrodisiac properties associated with high doses of Passiflora extract (Dhawan et al 2003a). A benzoflavone moiety may be chiefly responsible, as tests with this isolated compound were found to increase libido and fertility of males rats after 30 days' treatment (Dhawan et al 2002a).

Antitussive and anti-asthmatic activity

P. incarnata was as effective as codeine phosphate in suppressing a sulfur-dioxide-induced cough in mice (Dhawan&Sharma2002). Passionflower (100 mg/kg) was also able to prevent dyspnoea-related convulsions in guinea pigs with acetylcholine-induced bronchospasm (Dhawan et al 2003b).

DOSAGE RANGE

- Dried herb: 2 g three to four times daily.
- Infusion of dried herb: 0.25–2 g three to four times daily.
- Fluid extract (1:1) (g/mL): 2 mL three to four times daily in 150 mL of water.
- Tincture (1:5) (g/mL): 10 mL three to four times daily.

TOXICITY

Not known.

ADVERSE REACTIONS

Drowsiness is theoretically possible with excessive doses.

One human study found that Passiflora extract has a significantly lower incidence of impairment of job performance compared with oxazepam (Akhondzadeh et al 2001b). One case reports a 34-year-old woman who developed severe nausea, vomiting, drowsiness and episodes of non-sustained ventricular tachycardia following administration of passionflower at therapeutic doses (Fisher et al 2000).

SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of pharmacological activity and are theoretical.

Benzodiazepines

Additive effects are theoretically possible at high doses, although it may be a useful support during benzodiazepine withdrawal. Use with caution and monitor drug dosage — possible beneficial interaction under medical supervision.

Barbiturates

Additive CNS sedation is theoretically possible. Use with caution and monitor drug dosage — possible beneficial interaction under medical supervision.

CONTRAINDICATIONS AND PRECAUTIONS

None known.

PREGNANCY USE

Passionflower has demonstrated the ability to increase uterine contractions in an isolated rat uterus model when compared to control tissue (Sadraei et al 2003). Caution should be used until safety is better established.

PRACTICE POINTS/PATIENT COUNSELLING

- Both human and animal studies confirm passionflower has significant anxiolytic activity although more trials with larger numbers of participants are still needed to clarify its place in practice.
- One randomised study found that it has significantly less negative effects on performance than 30 mg oxazepam, yet is as effective for GAD.
- Maximal effects may require several days of regular intake.
- It is not known whether physical tolerance develops.
- One study has shown it improves psychological symptoms during opiate withdrawal when used together with clonidine.
- In practice, it is often prescribed with other herbs for stronger anxiolytic effect.

PATIENTS' FAQs

What will this herb do for me?

Passionflower may have an anxiolytic effect that can relieve restlessness and nervous tension. In higher doses, it is used for insomnia.

When will it start to work?

When being used for anxiety, it may take 3–4 weeks before significant effects are seen.

Are there any safety issues?

Overall, passionflower does not appear to impair job performance. However, it may theoretically interact with other sedative medicines when used in high doses. Other interactions are theoretically possible, so use should be monitored by a healthcare professional.

Pelargonium

HISTORICAL NOTE *Pelargonium sidoides* DC. (Geraniaceae) is an important traditional medicine in South Africa where it has been used to treat diarrhoea, dysentery, coughs and colds, tuberculosis and gastrointestinal conditions. This and other South African traditional medicines were often referred to by their original Khoi-Khoi name *rabas*, and were amongst the first to be recorded by early explorers such as van der Stel (1685) and Thunberg (1773). The most detailed account of the value and uses of *P. sidoides* is that of Smith (1895) who listed *P. reniforme/P. sidoides* as the first of five species used in the treatment of dysentery (Brendler & van Wyk 2008). The herb was introduced to Europe by the Englishman Charles Henry Stevens and is now a popular, commercially produced herbal medicine, listed in the European Pharmacopoeia (Brendler & van Wyk 2008).

COMMON NAME
South African geranium

OTHER NAMES
Geranium, EPs 7630, Geranien, Geranium Root, Ikhubalo, Icwayiba, i-Yeza lezikali, Kalwerbossie, Pelargonien, Pelargonium Root, Rabas, Rabassam, Silverleaf geranium, Umckaloabo, Uvendle

BOTANICAL NAME/FAMILY
Pelargonium sidoides/Geraniaceae

PLANT PARTS USED
Root

CHEMICAL COMPONENTS
Oligomeric and polymeric proanthocyanidins are present in significant amounts; the putative precursors afzelechin, catechin and gallocatechin have been isolated; and highly oxygenated coumarins. Gallic acid is consistently found in high concentrations in the plant material and the minerals calcium and silica (Kolodziej 2007, Kolodziej et al 2003).

Coumarins and phenolic compounds, including simple phenolic acids and proanthocyanidins, are the principal compounds found in the special extract, EPs ® 7630 (Kolodziej 2007). Gallic acid occurs in low amounts in EPs ® 7630 (Kolodziej 2007).

MAIN ACTIONS

Antibacterial activity
Different in-vitro evaluations of the herbal preparation from the roots of *P. sidoides* and its isolated constituents demonstrated pharmacological activities including moderate, direct antibacterial effects against a panel of pathogenic bacteria that are responsible for numerous respiratory tract infections, several multi-resistant strains of *Staphylococcus aureus*, also *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Moraxella catarrhalis* and *Mycobacterium tuberculosis* (Kolodziej et al 2003, Lizogub et al 2007, Mativandlela et al 2006).

Clinical note — Is it* P. sidoides *or* P. reniforme*?
P. sidoides is predominantly found over large parts of the interior of southern Africa, but also occurs in coastal mountain ranges. The product may be adulterated with the very similar-looking *P. reniforme* and the two species often grow side by side. The phytochemical composition of the roots of *P. sidoides* is similar to *P. reniforme*, reflecting the close botanical relationship between the two species (Brendler & van Wyk 2008, Kolodziej 2007). Morphological distinction of the dried product is extremely difficult and chemical analysis is the only reliable method of telling them apart.

Anti-adhesion properties
It has also demonstrated an inhibition of the interaction of group A streptococci and host epithelia, thereby reducing bacterial adhesion and/or invasion of epithelia.

Immune enhancement
The root extract also exhibits notable immune modulatory capabilities. The immune modulatory activities are mediated mainly by the release of tumour-necrosis factor (TNF-alpha) and nitric oxides, the stimulation of interferon-beta, the increase of natural killer cell activity and interferon-like activity (Kolodziej et al 2003, Lizogub et al 2007). Improved phagocytosis has also been demonstrated in vitro.

ANTIVIRAL ACTIVITY
Direct antiviral activity against herpesvirus 1 and 2 has been demonstrated (Schnitzler et al 2008). *P. sidoides* extract affects the virus before penetration into the host cell and reveals a different mode of action when compared to acyclovir and might be suitable for topical therapeutic use as antiviral drug both in labial and genital herpes infection. Through induction of the interferon (IFN) system and up-regulation of cytokines, important in protecting host cells from viral infection, the herb can be expected to exhibit antiviral activity in vivo (Engler et al 2009).

OTHER ACTIONS
The liquid extract acts as an expectorant and reduces sputum production, allowing the body to expel mucus thereby making conditions less suitable for the multiplication of the bacteria and viruses.

CLINICAL USE
Most research has been conducted with a standardised liquid herbal extract of the roots of *P. sidoides* (1:8–10), extraction solvent: ethanol 11% (wt/wt) produced by Willmar Schwabe Pharmaceuticals, Karlsruhe, Germany, also known as EPs 7630 (Trademark: Umckaloabo®, marketed by Spitzner Arzneimittel, Ettlingen, Germany).

Respiratory tract infections (RTIs)

In the light of inappropriate antibiotic use and increasing drug resistance rates worldwide, the need for an alternative, effective remedy for respiratory tract conditions is crucial. *P. sidoides* has been investigated as one such medicine and represents a promising treatment for the management of RTIs. Not yet widely used in most Western countries, it has achieved widespread popularity in Germany and is approved for the treatment of acute bronchitis, acute tonsillopharyngitis and acute sinusitis.

At least 17 reports of clinical trials have been published with *P. sidoides* in the treatment of various respiratory tract infections (Brendler & van Wyk 2008). The earliest trials were conducted in the 1990s and many were observational studies. More recent studies tend to be placebo-controlled randomised trials and focused on acute bronchitis, although observational studies are still performed. The results of the individual research reports are compelling, particularly as there are no good treatment options for viral RTIs and bacterial RTIs are becoming increasingly difficult to treat.

In a 2008 Cochrane systematic review, authors evaluated data from eight randomised control trials (RCTs) and concluded that *P. sidoides* may be effective in alleviating symptoms of acute rhinosinusitis and the common cold in adults, but the findings are not yet definitive (Timmer et al 2008). They identified two RCTs that showed *P. sidoides* was effective in relieving all symptoms, and in particular cough and sputum production in adults with acute bronchitis although a third study showed that the preparation was only effective for treating sputum reduction. Similarly, *P. sidoides* was effective in resolving symptoms of acute bronchitis in two out of three paediatric studies. In acute sinusitis and the common cold, *P. sidoides* was effective in resolving all symptoms, including headaches and nasal discharge, in adults when taken for an extended time period.

Two RCTs used tablet forms and all others used liquid herbal extracts. Based on this, the authors stated that the liquid preparation (alcoholic solution) may be associated with improvement in some symptoms of acute bronchitis in both children and adults, in particular sputum production and cough, but fewer or no potential beneficial effects were seen in both children and adults taking the tablets when tested. The cause of this difference is unknown and may be due to chance or differences in constituent bioavailability or in the product's phytochemical constituents.

The same year, a review was published in *Phytomedicine* that analysed six RCTs, of which four were suitable for statistical pooling (Agbabiaka et al 2008). One study compared EPs 7630 against conventional non-antibiotic treatment (acetylcysteine); the other five studies tested EPs 7630 against placebo. All RCTs reported findings suggesting the effectiveness of EPs 7630 in treating acute bronchitis. When meta-analysis of the four placebo-controlled RCTs was conducted, the results confirmed that EPs 7630 significantly reduced bronchitis symptom scores in patients with acute bronchitis by day 7.

The most recent RCT was published in 2007 and was a randomised, double-blind, multi-centre study by Lizogub et al (2007). It demonstrated that treatment with liquid extract of *P. sidoides* significantly hastened recovery from the common cold, and markedly improved individual symptoms, most notably nasal congestion and drainage, sneezing, sore throat, hoarseness and headache. The group receiving active treatment also experienced significantly higher remission and improvement in rates of other cold-related symptoms compared to placebo, such as limb pain (95.5% vs 74%), general weakness (79% vs 35%), exhaustion (85% vs 43%) and fatigue (89% vs 60.5%) (Lizogub et al 2007). The study of 103 adults compared 30 drops (1.5 ml) of liquid herbal pelargonium three times daily to placebo for a maximum of 10 days. After this period, substantially more people receiving the herbal treatment were considered as clinically cured than the placebo group (78.8% vs 31.4%; $P < 0.0001$). All (100%) of patients receiving pelargonium judged tolerability of treatment as good or very good.

Other uses

The traditional uses of tuberous *Pelargonium* species mainly involve ailments of the gastrointestinal tract (diarrhoea and dysentery) and respiratory tract although Smith (1895) made a case for it being used as a general tonic.

Clinical note — The difficult and winding road to successful commercialisation

It is believed that the medicinal properties of *Pelargonium sidoides* were first recognised and applied by traditional tribal healers in South Africa many centuries ago. It first came to the attention of Europeans in the early 1900s, as a result of a serendipitous meeting between an Englishman, Charles Henry Stevens, and a traditional Zulu healer. In 1897, Stevens was sent to South Africa by his doctor to recover from pulmonary tuberculosis. Whilst there, he was treated by a traditional Zulu healer with a root concoction that successfully cured his condition (Bladt & Wagner 2007). Seeing the need for such a medicine back home and no doubt the commercial opportunity, Stevens called the tuberculosis treatment 'Umckaloabo' which he commercially manufactured once back in England. The treatment also became known as the 'Stevens' Cure' and caused controversy amongst the medical establishment, which sought to discredit him by labelling Stevens a 'quack'. After his death in 1942, Stevens' son sold the business to a drug manufacturer in Germany. The exact herbal ingredient in the remedy and its source was kept secret and shrouded in mystery until well into the 1970s when the plant ingredient was finally identified as *P. sidoides* by S. Bladt whilst undertaking research for her thesis in Germany (Bladt & Wagner 2007). After the conduct of scientific and clinical trials, the herb was once again commercially manufactured in Europe with great success, with an annual turnover in Germany of 80 million Deutschmark in 2006 (Brendler & van Wyk 2008).

It is also used as a gripe water for infants ('upset stomach', 'with air in the intestine'). The crushed root is mixed with water and a teaspoonful of the red infusion is taken orally (Brendler & van Wyk 2008).

The aerial parts have also been used traditionally as a wound-healing agent. This may due to their high tannin content that would contribute to its astringent effect (Kolodziej 2007).

DOSAGE RANGE

Dried herb: 0.4 g/day

According to clinical studies

- Acute treatment of respiratory tract infections.
- Adults and children over 12 years: 30 drops (1.5 ml) of liquid extract herbal pelargonium three times daily before meals for up to 10 days.
- Children aged 6–12 years: 20 drops (1.0 ml) three times per day.
- Observational studies have suggested that children under the age of 6 years may take 0.5 ml three times per day.

TOXICITY

Not known

ADVERSE REACTIONS

Overall, in all clinical and observational studies, *P. sidoides* showed a good tolerability with no serious adverse events reported (Lizogub et al 2007). A meta-analysis of eight RCTs reported that adverse events are slightly more frequent with *P. sidoides* than placebo. Besides gastrointestinal complaints such as nausea, vomiting, diarrhoea or heartburn, allergic skin reactions with pruritus and urticaria have been reported in trials (Timmer et al 2008).

De Boer et al (2007) reported that the Uppsala Monitoring Centre has, through the world health organisation (WHO) international pharmacovigilance programme, received 34 case reports of allergic reactions suspected to be associated with the use of Pelargonium extract, all originating from Germany (de Boer et al 2007). These include 12 cases of severe, life-threatening anaphylaxis. Although proof of causality is not established for each of these cases, the report describes a signal that merits further study and validation.

SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

Immunosuppressant drugs

Theoretically, use of this herb may reduce the effectiveness of immunosuppressant medication — avoid until safety can be established.

CONTRAINDICATIONS AND PRECAUTIONS

People with an allergy to the geranium family of plants should avoid this herb.

PREGNANCY USE

Insufficient reliable information available to determine safety.

PRACTICE POINTS/PATIENT COUNSELLING

- *P. sidoides* is a traditional herbal medicine originating from South Africa and now extremely popular in Europe, particularly Germany.
- The herb demonstrates antibacterial activity and enhances immune function, also activity against herpesvirus 1 and 2.
- Observational and randomised studies suggest that it may be useful in the acute treatment of respiratory infections, particularly bronchitis.
- It appears to hasten recovery from the common cold, reduce symptoms and improve associated fatigue and weakness and may have a role in the acute treatment of other, uncomplicated respiratory infections.
- It is generally well tolerated; however, gastrointestinal side effects and allergic skin reactions have been reported with use.

PATIENTS' FAQs

What will this herb do for me?

Pelargonium sidoides can enhance immune function and hasten recovery from respiratory tract infections such as bronchitis, whilst improving symptoms.

When will it start to work?

When used as acute treatment of the common cold, symptom relief may be noticeable within 3 days and significant after 5 days.

Are there any safety issues?

It is generally well tolerated; however; gastrointestinal side effects and allergic skin reactions have been reported with use.

Peppermint

HISTORICAL NOTE The written record of mint dates back to an ancient Greek myth in which the Greek god Pluto was said to have affections for a beautiful nymph named Minthe. His jealous wife Persephone cast a spell on the nymph, transforming her into a plant. When Pluto could not reverse the spell, he gave her a sweet scent that would emanate throughout the garden (Murray & Pizzorno 1999). Peppermint has been used medicinally for generations as a digestive aid and carminative. More recently, enteric-coated peppermint oil capsules have been widely prescribed for the relief of irritable bowel syndrome (IBS).

BOTANICAL NAME/FAMILY

Mentha × *piperita* (family [Labiatae] Lamiaceae)

PLANT PARTS USED

Leaf or stem — essential oil is distilled from the aerial parts.

CHEMICAL COMPONENTS

Peppermint leaves contain about 2.5% essential oil, 19% total polyphenolic compounds, 12% total flavonoid compounds (eriocitrin, luteolin-7-*O*-rutinoside and hesperidoside) and 7% total hydroxycinnamic compounds (including rosmarinic acid) (Duband et al 1992). The biochemistry, organisation and regulation of essential oil metabolism in the epidermal oil glands of peppermint have been defined, and research is underway to create 'super' transgenic peppermint plants with improved oil composition and yield (Wildung & Croteau 2005).

Essential oil

Over 100 constituents have been identified in peppermint oil. The principal constituents are menthol (35–55%), menthones (10–35%), isomenthone, menthyl acetate, menthofuran and cineole. To comply with the European Pharmacopoeia, the oil must not contain more than 4% pulegone and not more than 1% carvone.

MAIN ACTIONS

The actions of the leaf as an infusion or liquid extract are largely dependent on the essential oil content. Other compounds, such as the flavonoids, also contribute to the overall activity, especially the antioxidant and anti-allergic activities. Peppermint oil is relatively rapidly absorbed after oral administration and eliminated mainly via the bile (Grigoleit & Grigoleit 2005a).

Antispasmodic

Peppermint oil, ethanol extracts and flavonoids isolated from the leaf have all been shown to have antispasmodic (spasmolytic) effects in vitro (ESCOP 1997) with the effect mediated via smooth muscle calcium channels (Hills & Aaronson 1991). Newer research has shown that menthol induces Ca^{2+} ion influx in a subset of sensory neurons from dorsal root and trigeminal ganglia, due to the activation of TRPM8, a Ca^{2+}-permeable cold-activated member of the TRP superfamily of cation channels. Although menthol has been shown to induce Ca^{2+} release from intracellular stores in several TRPM8-expressing cell types, which would suggest that TRPM8 functions as an intracellular Ca^{2+} release channel, a TRPM8-independent pathway of Ca^{2+} release, originating from the endoplasmic reticulum and the Golgi compartments, has recently been postulated (Kim et al 2009, Mahieu et al 2007).

In healthy volunteers, intragastric administration of a dose equivalent to 180 mg peppermint oil reduced intraoesophageal pressure within 1–7 min of infusion (Kingham 1995), while in nine human studies involving 269 subjects, peppermint oil produced substantial spasmolytic effects on the smooth muscles of the gastrointestinal tract when used topically (intraluminal) or orally in doses of 0.1–0.24 mL (Grigoleit & Grigoleit 2005b). Enteroplant, an enteric-coated capsule containing 90 mg peppermint and 50 mg caraway oil, has also been shown to act locally in the stomach and duodenum to produce smooth muscle relaxation (Micklefield et al 2003). Peppermint oil has also been shown to have similar antispasmodic activity on the colon to the Chinese herbal medicine shakuyaku-kanzo-to (TJ-68), as observed by direct observation during colonoscopy (Ai et al 2005). Moreover, while investigating the effects of herbal extracts on the frequency and amplitude of slow waves in the small intestine, it was found that peppermint leaf reduces the frequency but leaves the amplitude unchanged (Sibaev et al 2006).

Carminative

Peppermint has a carminative activity, which refers to its ability to relax the gastrointestinal sphincters. Carminatives are thought to alleviate symptoms of bloating and gas by facilitating eructation and passage of flatus. The classic carminatives are essential oils, such as spearmint and peppermint. Studies from the 1950s on the effect of carminatives on the gut suggest that they work by inducing relaxation of the lower oesophageal sphincter (LES) (Massey 2001). A later study has shown that peppermint oil canalised into the gall bladder and duodenal areas was able to counteract morphine hydrochloride-induced constriction of the sphincter of Oddi (Giachetti et al 1988).

Choleretic

Choleretic activity has been demonstrated for peppermint tea, flavonoids and the essential oil in dogs and rats (ESCOP 1997). Hydrophilic compounds may contribute to the gastrointestinal effects, with aqueous extracts from peppermint leaves having antiulcerogenic and choleretic effects (Grigoleit & Grigoleit 2005c, Van Rensen 2004). Peppermint oil has been shown to have a relaxing

effect on the gall bladder and small intestine, producing complete inhibition of gall bladder emptying and prolonged orocaecal transit time comparable to that produced by *N*-butylscopolamine (Goerg & Spilker 2003).

Antimicrobial

Antibacterial

Peppermint oil has been shown to have a significant antibacterial activity (Mimica-Dukic et al 2003), as has the juice of peppermint leaves (Rakover et al 2008, Saeed & Tariq 2005). Peppermint oil has been shown to inhibit *Helicobacter pylori*, *Staphylococcus aureus* (Betoni et al 2006, Imai et al 2001, Mohsenzadeh 2007, Yadegarinia et al 2006), *Escherichia coli* (Mohsenzadeh 2007, Pattnaik et al 1995, Yadegarinia et al 2006), *Salmonella enteritidis*, *Listeria monocytogenes* and multiresistant strains of *Shigella sonnei* and *Micrococcus flavus* (Mimica-Dukic et al 2003). When investigating anti-*Staphylococcus aureus* activities, synergistic effects between peppermint extract and various antimicrobial drugs were found (Betoni et al 2006).

Fungistatic, fungicidal

Peppermint is also fungistatic and fungicidal (Pattnaik et al 1996, Positive Health News 1998) with its activity against *Trichophyton tonsurans*, *Candida albicans* and other micromycetal food poisoning, plant, animal and human pathogens being considerably greater than the commercial fungicide bifonazole but lower than that of *Thyme* spp (Mimica-Dukic et al 2003, Sokovic et al 2009, Yadegarinia et al 2006). Fungicidal activity similar to lavender and clove oil was reported for peppermint oil against *Trichophyton mentagrophytes* when used in combination with salt and heat (Inouye et al 2007). Peppermint oil showed high antifungal activity against *Candida albicans* (Yigit et al 2008), with one study reporting a 74% *Candida albicans* (strain CA I) biofilm reduction due to the effects of peppermint oil (Agarwal et al 2008). Moderate antifungal activity was observed for peppermint oil against *Rhizopus stolonifer*, *Botrytis cinerea*, *Aspergillus niger*, *Aspergillus candidus*, *Penicillium* spp and *Fusarium culmorum* (Behnam et al 2006, Magro et al 2006). Moreover, peppermint oil at various concentrations has shown to inhibit aflatoxin B production by 85–90% when evaluated for activity against *Aspergillus parasiticus* and *Aspergillus flavus* (Bluma et al 2008). Peppermint oil and its main constituent menthol have also been shown to have significant antibacterial, antifungal and antiplasmid activity and to potentiate the antibiotic effect of oxytetracycline (Schelz et al 2006).

Peppermint oil has further been shown to have a significant antimycobacterial activity in vitro, and inhalation of peppermint oil has been successfully used as a supplement to combined multidrug therapy for pulmonary tuberculosis (Shkurupii et al 2002). In a recent study, peppermint oil showed stronger antimicrobial and antibiofilm properties than chlorhexidine against *Streptococcus mutans* and *Streptococcus pyogenes* (Rasooli et al 2008).

Antiviral

Peppermint oil also has virucidal activity against herpes simplex virus (HSV)-1 and -2, including activity against an acyclovir-resistant strain of HSV-1 (ACV_{res}) with a 50% inhibitory concentration determined at 0.002 and 0.0008% for HSV-1 and HSV-2, respectively. The oil was also found to affect the virus before, but not after, penetration into the host cell (Schuhmacher et al 2003). Aqueous extract (Geuenich et al 2008, Nolkemper et al 2006) and 80% ethanolic extract of peppermint (Reichling et al 2008) at maximum noncytotoxic concentrations reduced plaque formation of HSV-1, HSV-2 and ACV_{res} significantly following exposure of free virions as well as host cells to the extracts prior to infection.

Insecticidal

Peppermint oil showed moderate repellent activity against *Culex pipiens* (Erler et al 2006), and menthol and its derivatives showed mosquitocidal activity against *Culex quinquefasciatus*, *Aedes aegypti* and *Anopheles tessellatus* (Samarasekera et al 2008). Peppermint oil was shown to only exert some repellence against head lice (*Pediculus humanus* var. *capitis*), which was due to the slippery nature of the oil rather than specific repellent activity (Canyon & Speare 2007). However, a combination product of 5% eucalyptus and 5% peppermint oil in 50% ethanol showed effectiveness against the head lice (Gonzalez Audino et al 2007).

Antiparasitic

Aqueous extracts of peppermint showed activity against gastrointestinal nematodes in goats and pigs (De Almeida et al 2007, Lans et al 2007). In vitro, dichlormethane extracts, but not water extracts, of peppermint showed antigiardial activity by causing alterations on the plasma membrane surface of the parasite and inhibiting its adhesion (Vidal et al 2007).

Anti-allergic

A 50% hydroethanolic extract of peppermint leaves inhibited chemically induced histamine release from rat peritoneal mast cells in vitro. The peppermint extract was also shown to reduce nasal symptoms (sneezing and nasal rubbing) in rats with experimentally induced allergic rhinitis. Significant inhibition of sneezing and nasal rubbing was observed at oral doses of 300 and 1000 mg/kg, respectively (Inoue et al 2001).

The flavonoid luteolin-7-*O*-rutinoside isolated from the aerial parts of peppermint has been shown to inhibit histamine release from rat peritoneal mast cells in a dose-dependent manner (100–300 mg/kg) and to reduce antigen-induced allergic nasal symptoms (Inoue et al 2002), although it would be difficult to achieve such doses of luteolin with a commercially available peppermint extract or oil. An extract of the whole herb, however, may be beneficial in alleviating nasal symptoms associated with allergic rhinitis in association with other medicines.

Antioxidant

The polyphenolic compounds in peppermint, such as luteolin-7-*O*-rutinoside, eriocitrin and rosmarinic acid, have been shown to have antioxidant and free radical scavenging activity (Sroka et al 2005). Peppermint oil and its constituents menthone and isomenthone exert antioxidant activity (Mimica-Dukic et al 2003). Interestingly, peppermint and lemon balm exerted the strongest antioxidant and radical scavenging effects when examining all individual herbs from a herbal combination preparation (STW5 — Iberogast: 9 plant extracts from *Mentha piperita*, *Iberis amara, Chelidonii herba*, *Cardui mariae fructus*, *Melissae folium*, *Carvi fructus*, *Liquiritiae radix*, *Angelicae radix*, *Matricariae flos*) (Germann et al 2006, Schempp et al 2006).

Stimulant

Intraperitoneal and intravenous injections of peppermint oil and its constituents, 1,8-cineol, menthone, isomenthone, menthol, pulegone, menthyl acetate and caryophyllene, dramatically increased ambulatory activity in mice, which may explain the traditional use of peppermint for mental fatigue (Umezu & Morita 2003, Umezu et al 2001). A recent study suggests that this effect exerted by menthone is mediated via dopamine (Umezu 2009). Inhalation of peppermint oil has also been shown to have a stimulant effect on mice in a forced swimming test, with the effect remaining when over-agitation was induced by intraperitoneal caffeine (Lim et al 2005).

Coolant

Peppermint oil interacts with smooth muscle calcium channels (Hills & Aaronson 1991). In the peripheral nerves, this effect may be responsible for the characteristic cooling sensation experienced on oral ingestion of mint.

Analgesic

Peppermint and caraway oil have been shown to synergistically modulate postinflammatory visceral hyperalgesia in a rat model (Adam et al 2006). A significant analgesic effect, with a reduction in sensitivity to headache, was observed in a double-blind, placebo-controlled, randomised, 7-day cross-over study that used a combination of peppermint oil and ethanol applied externally in 32 healthy males undergoing artificial pain stimulation (Gobel et al 1994).

PROTECTS AGAINST RADIATION-INDUCED TOXICITY

Mentha piperita protects against radiation-induced lethality, lipid peroxidation and DNA damage (Jagetia 2007) through its antioxidant and free radical scavenging activities (Samarth et al 2006b). The same authors suggest that these activities are also responsible for a significant reduction in the number of lung tumours observed in mice following oral administration of peppermint extract (Samarth et al 2006a). It has also been reported that peppermint protected against radiation-induced haematopoietic damage in bone marrow of mice by increasing erythropoietin levels (Samarth 2007). In prostate cancer cells, menthol-induced cell death was not associated with Ca^{2+} influx pathways (Kim et al 2009).

OTHER ACTIONS

A spray-dried peppermint infusion has been found to be mildly diuretic and produce weak sedative action in several tests when administered orally to mice (Della et al 1990). Peppermint tea has been found to significantly increase follicle stimulating hormone (FSH) and luteinising hormone (LH) levels and reduce total testosterone levels in rats (Akdogan et al 2004). Concomitant topical exposure to low concentrations of peppermint oil reduced the percutaneous penetration of benzoic acid; however, with increased peppermint oil doses, penetration of benzoic acid increased (Nielsen 2006). Peppermint extract was shown to reduce the side effects of arsenic-induced hepatopathy (Sharma et al 2007). In a recent study, peppermint oil displayed acetylcholinesterase and butyrylcholinesterase inhibitory activities, which was more than the activity exerted by individual components of the oil (Orhan et al 2008).

CLINICAL USE

In practice, peppermint and its derivatives are used in many forms and administered by various routes. This review will focus only on those methods that are commonly used by the public and preparations that are available over the counter (OTC), such as oral dose forms, topical applications and inhalations.

IBS

There have been several studies examining the effects of peppermint oil in the treatment of IBS (Dew et al 1984, Rees et al 1979). Newer studies have tended to use pH-triggered, enteric-coated peppermint oil capsules that prevent dissolution of the capsules until they have reached the small intestine, and release into the colon is extended over 10–12 hours (Grigoleit & Grigoleit 2005c). Enteric coating allows administration of a higher dose than would otherwise be possible to tolerate and, importantly, avoids the risk of excessively relaxing the lower oesophageal sphincter and causing reflux.

A critical review and meta-analysis of peppermint oil for IBS performed in 1998, which included five double-blind trials, concluded that peppermint oil is efficacious for symptom relief in IBS but that there was insufficient evidence to claim benefit beyond reasonable doubt (Pittler & Ernst 1998). A 2005 review identified 16 clinical trials investigating peppermint oil in IBS. Of these, eight of 12 placebo-controlled studies showed statistically significant effects in favour of peppermint oil, with an average response for 'overall success' being 58% for peppermint oil and 29% for placebo. Three studies that compared peppermint oil to smooth muscle relaxants showed no difference between these treatments (Grigoleit & Grigoleit 2005a). Since then, one randomised double-blind study involving 57 patients with IBS without bacterial overgrowth found that treatment with two enteric-coated capsules of peppermint oil twice

daily (Mintoil) for 4 weeks produced statistically significant improvement in diarrhoea, abdominal bloating, constipation, lower abdomen pain, pain on defecation, feeling of incomplete evacuation and difficulty on evacuation (Cappello et al 2006, 2007). One recent review showed that peppermint oil and fibre were more effective than placebo in the treatment of IBS (Ford et al 2008). Moreover, another recent review concluded that peppermint oil seems to be the most promising agent for the treatment of IBS (NNT 2.5). Although this conclusion was only based on the results of four trials (n = 400), there was only little heterogeneity between the three high quality trials and no significant adverse effects were reported (Jones 2008). Two reviews summarise the evidence for pharmacological interventions for recurrent abdominal pain and IBS in children (Banez 2008, Huertas-Ceballos et al 2008); however, both of these reviews refer to only one trial so far conducted in children, thus highlighting the need for more research in the area. In the cited, randomised, double-blind, controlled trial of 42 children with IBS, treatment with enteric-coated peppermint oil capsules reduced the severity of the pain in 75% of the children (Kline et al 2001).

Bacterial overgrowth of the small intestine is associated with a number of functional somatic disorders, including IBS, fibromyalgia and chronic fatigue syndrome (CFS). There have been two reports of successful treatment of IBS due to intestinal overgrowth with enteric-coated peppermint oil capsules. This clinical effect may in part be associated with the antimicrobial activities of peppermint oil (Gaby 2003, Logan & Beaulne 2002).

Clinical note — Pathophysiology of IBS

The pathophysiology of IBS is poorly understood, but it is believed to occur when the intestinal muscles are contracting faster or more slowly than normal. Colonic contractions cause abdominal pain, cramping, wind and diarrhoea or constipation. It has been proposed that IBS may result from dysregulation of gastrointestinal motor and enhanced sensory functions, as modulated by the central nervous system (CNS). However, clinical and laboratory investigations have failed to uncover any histological, microbiological or biochemical abnormalities in patients with IBS. Patients with IBS demonstrate increased motility and abnormal contractions of the intestinal muscles when faced with an emotionally or physically stressful situation (Greenberg et al 2002). It is likely that IBS is also associated with dietary habits, poor upper digestion and intestinal dysbiosis (bacterial overgrowth of the bowels).

Common symptoms of IBS are (Greenberg et al 2002) as follows:

- cramping pain in the lower abdomen
- bloating and excess gas (wind)
- changes in bowel habits
- diarrhoea or constipation, either one dominant or both alternating
- immediate need for a bowel movement on awakening or during or after meals
- relief of pain after bowel movements
- feeling of incomplete emptying after bowel movements
- mucus in the stool.

Dyspepsia

A two-way crossover study with 10 healthy male volunteers showed that peppermint oil enhances gastric emptying during the early phase (decrease in T lag and beta constant), suggesting the potential use of peppermint oil in functional gastrointestinal disorders (Inamori et al 2007).

In a systematic review of herbal medicines for functional dyspepsia, Coon & Ernst (2002) found 17 randomised clinical trials, 9 of which involved peppermint and caraway combination preparations, with 60–95% of patients reporting improvements in symptoms.

An enteric-coated capsule (Enteroplant) that contains 90 mg peppermint oil (WS-1340) and 50 mg caraway oil (WS-1520) has been shown in a double-blind, placebo-controlled, multicentre trial with 45 patients to significantly improve symptoms of nonulcer dyspepsia. Nearly 90% of patients experienced a reduction in pain, and after 4 weeks, nearly 95% had improved their Clinical Global Impression scores. Before the start of treatment, all patients in the test preparation group reported moderate to severe pain, while by the end of the study 63.2% of these patients were free of pain. The peppermint and caraway oil combination was well tolerated (May et al 1996).

Since then, there have been three further randomised placebo-controlled trials of this particular peppermint–caraway oil combination. In one trial with 223 patients with nonulcer dyspepsia and IBS, the peppermint oil combination was found to significantly reduce pain compared to placebo ($P < 0.001$) (Freise & Kohler 1999). In a further study of 96 outpatients, the same peppermint formulation was found to significantly improve symptoms of functional dyspepsia. After 4 weeks, the average intensity of pain was reduced by 40% versus baseline in the active group and by 22% in the placebo group. The peppermint combination also reduced pressure, heaviness and fullness (May et al 2000). A subgroup analysis from this study revealed that *Helicobacter pylori*-positive patients had a substantially better treatment response, although those who were negative to *H. pylori* also showed significant improvements compared to those receiving placebo (May et al 2003). In a further double-blind placebo-controlled trial, the same oil combination was found to significantly improve disease-specific quality of life (QOL), as measured by the validated Nepean Dyspepsia Index compared to placebo (Holtmann et al 2003).

The same peppermint and caraway oil combination has been compared with cisapride (Prepulsid), which increases the LES pressure, thereby reducing the risk of reflux. Cisapride is also used to treat IBS dominated by constipation but has been linked to serious cardiac arrhythmias and should be used with caution. In the 4-week study, the peppermint and

caraway oil combination (Enteroplant, 2 capsules daily) was shown to be as effective as cisapride in reducing both the magnitude and the frequency of pain. Physicians rated the two treatments comparable in regard to other dyspeptic symptoms, in addition to intestinal and extraintestinal autonomic symptoms. Corresponding results were also found in *H. pylori*-positive patients and patients who initially presented with intense epigastric pain in the two treatment groups. Both medications were well tolerated (Madisch et al 1999).

A combination herbal preparation (STW5 — Iberogast) that includes peppermint leaf extract and eight other plant extracts (*Iberis amara*, *Chelidonii herba*, *Cardui mariae fructus*, *Melissae folium*, *Carvi fructus*, *Liquiritiae radix*, *Angelicae radix* and *Matricariae flos*) has been demonstrated to significantly relieve dyspepsia in a number of randomised controlled trials (RCTs), including a meta-analysis of three trials (Melzer et al 2004), with a fourth RCT showing similar effects to cisapride (Rosch et al 2002). In a newer study, it was shown that STW5 lowered gastric acidity as effectively as commercial antacid preparations (i.e. Rennie, Talcid and Maaloxan), prevented secondary hyperacidity more effectively and additionally inhibited serum gastrin levels in rats (Khayyal et al 2006).

Diffuse oesophageal spasm

Diffuse oesophageal spasm (DES) is a relatively rare motor disorder. Associated manometric abnormalities may include hypertensive and repetitive contractions. The LES may also be hypertensive. Although LES relaxation with deglutition is generally normal, disturbances in LES function are often seen. These abnormalities are, however, not required for the diagnosis (Massey 2001). In a study of eight DES patients with chest pain or dysphagia, peppermint oil had no effect on LES pressures or contractile pressures and durations in the oesophagus, yet completely eliminated simultaneous oesophageal contractions in all patients ($P < 0.01$). The number of multiphasic, spontaneous and missed contractions also improved. Two of the eight patients had their chest pain resolved after taking the peppermint oil (Pimentel et al 2001).

Antispasmodic

The results from a randomised, double-blind, double-dummy, controlled trial suggest that the antispasmodic properties of peppermint oil can be utilised intraluminally during upper endoscopy with superior efficacy and fewer side effects than hyoscine-*N*-butylbromide (Buscopan) administered by intramuscular injection (Hiki et al 2003a, 2003b). The peppermint oil solution was subsequently used to successfully extend an endoscope past an area of severe antral stenosis in a case that was unresponsive to Buscopan. A further study of 383 patients receiving double-contrast barium enemas, which compared peppermint oil in the barium, peppermint oil in the enema tube, Buscopan and no treatment, found that peppermint oil in the barium or the enema tube could be safely and effectively used instead of Buscopan and that the oil had a stronger antispasmodic effect in the caecum and the ascending colon than a Buscopan injection (Asao et al 2003). Similarly, orally administered peppermint oil was an effective and safe antispasmodic agent for double-contrast barium meal examination in a controlled study with 420 participants (Mizuno et al 2006). In another study ($n = 40$), peppermint oil (20 mL, 1.6%) was effective and safe in inhibiting duodenal motility during endoscopic retrograde cholangiopancreatography, but additional administration was recommended for future procedures. The effect was identical to that of glucagon (Yamamoto et al 2006).

Headache

A solution of 10% peppermint oil in ethanol has been shown in a randomised, placebo-controlled, double-blind, crossover study to efficiently alleviate tension-type headache. The study analysed 164 headache attacks in 41 patients of both sexes ranging between 18 and 65 years of age, suffering from tension-type headache. The peppermint oil was spread largely across forehead and temples and repeated after 15 and 30 min. Using a headache diary, the headache parameters were assessed after 15, 30, 45 and 60 min. Compared with the application of a placebo, the peppermint oil significantly reduced the intensity of the headache after 15 min ($P < 0.01$). The analgesic effect of the peppermint oil was comparable to 1000 mg paracetamol (acetaminophen). Simultaneous ingestion of 1000 mg of paracetamol and application of 10% peppermint oil in ethanol solution led to a slight additive effect (Gobel et al 1996).

Postoperative nausea

Inhalation of peppermint oil vapours has been shown in a study to reduce postoperative nausea in gynaecological patients in a placebo-controlled trial in which patients were free to inhale peppermint oil as frequently as desired (Tate 1997). A hot peppermint oil compress is used in China to prevent abdominal distension in postoperative gynaecological patients (Feng 1997). In another placebo-controlled trial, a reduction in postoperative nausea was seen equally with inhalation of isopropyl alcohol, peppermint oil or saline, with the authors attributing the effect to the controlled breathing used during inhalation (Anderson & Gross 2004).

Respiratory tract infections

Peppermint and menthol have an established tradition in the treatment of respiratory infections. Chest rubs containing menthol are frequently used to treat coughs and bronchitis. Inhalation of various antiseptic and anti-inflammatory essential oils is often used in the treatment of respiratory infections, including bronchitis (Shubina et al 1990). In a recent study conducted with 18 healthy volunteers, it was shown that menthol inhalation did not affect nasal mucosal temperature and nasal airflow but supported the fact that menthol leads to direct stimulation of cold receptors modulating the cool sensation, thus inducing a feeling of clear and open nasal passages (Lindemann et al 2008).

Peppermint oil has been found to have a pronounced antimycobacterial effect in vitro, and long-term use of peppermint oil in a humidifier has been used in Ukraine as an adjunctive treatment to multidrug therapy for pulmonary tuberculosis (Shkurupii et al 2002). A more recent study shows that inhaling peppermint oil by patients with infiltrative pulmonary tuberculosis in the penitentiary system was most effective in the phase of resorption of infiltrates and/or closure of decay cavities (Shkurupii et al 2006).

Enhance cognitive performance

A combination of peppermint oil, eucalyptus oil and ethanol was shown in a crossover double-blind study to increase cognitive performance and promote relaxation in 32 healthy subjects (Gobel et al 1994). Peppermint odour has also been shown to reduce daytime sleepiness (Norrish & Dwyer 2005) and fatigue and to improve mood (Goel & Lao 2006), as well as significantly improve performance in difficult tactile tasks (Ho & Spence 2005) and promote a general arousal of attention with improved typing speed and accuracy (Barker et al 2003). Similarly, in a recent study with healthy volunteers (n = 144), peppermint oil inhalation enhanced memory and alertness (Moss et al 2008).

OTHER USES

Peppermint or pure menthol is commonly used in heat rub ointments for arthritis, fibromyositis, tendonitis and other musculoskeletal conditions. Commission E approved peppermint oil externally for neuralgia and myalgia (Blumenthal et al 2000). A case report describes the treatment of postherpetic neuralgia with the direct application of undiluted peppermint oil containing 10% menthol to the affected area. The pain relief persisted for 4–6 h after application of the oil. At a 2-month follow-up, the patient had only minor side effects and continued to use the medication (Davies et al 2002). An aromatherapy acupressure intervention using peppermint oil displayed positive effects on hemiplegic shoulder pain, compared to acupressure alone, in patients with stroke (Shin & Lee 2007).

An oral spray or gargle containing a range of essential oils including peppermint oil is reported to reduce snoring in one double-blind study (Prichard 2004). A mixture of tea tree, peppermint and lemon oil seemed effective in reducing malodour and volatile sulphur compounds in intensive care unit patients (Hur et al 2007).

Two studies conducted with breastfeeding women found that topical application of peppermint water and peppermint gel prevented nipple cracks and associated pain more effectively than lanolin and placebo (Melli et al 2007a, 2007b).

A small study (n = 44) conducted with patients undergoing breast cancer treatment showed that 18 of them (41%) chose peppermint and neroli hydrolat spray over plain water spray to manage their hot flashes (Dyer et al 2008).

Antimicrobial and antibiofilm properties of peppermint oil against *Streptococcus mutans* and *Streptococcus pyogenes* were evident, when an in-vivo study with healthy volunteers showed that brushing teeth with peppermint oil-blended toothpastes was more effective than using a chlorhexidine mouthwash (Shayegh et al 2008).

Traditional uses

Traditionally, peppermint was believed to increase libido and used to stop hiccups, relieve pain in childbirth, reduce bleeding and treat menorrhagia (Fisher & Painter 1996). It was also used externally to repress lactation, to treat dermatological conditions, as a mouthwash for painful gums and mouth and applied to the temples to relieve headaches.

DOSAGE RANGE

Leaf

- Infusion: 3–6 g three times daily (Blumenthal et al 2000).
- Liquid extract (1:2): 1.5–4.5 mL/day.

These dosages are for adults; adjust according to size for children.

Essential oil

- Digestive disorders: 0.2–0.4 mL three times daily in dilute preparations or in suspension (ESCOP 1997).
- IBS: 0.2–0.4 mL three times daily in enteric-coated capsules or tablets (Dew et al 1984, Rees et al 1979).
- Inhalation: 3–4 drops added to hot water.
- Lozenge: 2–10 mg.
- External use (for analgesic, anaesthetic or antipruritic activity): 0.1–1.0% m/m (ESCOP 1997).
- External use (counterirritant): 1.25–16% m/m (ESCOP 1997).

ADVERSE REACTIONS

A single dose of 4000 mg/kg of a spray-dried infusion did not produce any macroscopic signs of toxicity in mice (Della et al 1990). Peppermint oil taken orally has been shown to be well tolerated at the commonly recommended dosage but may cause significant adverse effects at higher doses (Kligler & Chaudhary 2007).

Short-term and subchronic oral studies reported brain lesions in rats that were given very large doses of peppermint oil containing pulegone, pulegone alone or large amounts (>200 mg/kg/day) of menthone. Pulegone is also a recognised hepatotoxin, and large doses of peppermint oil have been shown to be hepatotoxic in cultured human hepatoma cells (Vo et al 2003). Peppermint oil was negative in an Ames test and a mouse lymphoma mutagenesis assay but gave equivocal results in a Chinese hamster fibroblast cell chromosome aberration assay. There is a case report of acute lung injury following intravenous injection of peppermint oil (Behrends et al 2005).

Although sensitisation to peppermint oil and/or its constituents has been reported, a solution containing 8% peppermint oil was shown not to be a sensitiser (Nair 2001). Cases of allergic contact dermatitis to peppermint and menthol have been reported following intraoral application (Morton et al 1995, Tamir et al 2005), with one case reporting

vulval allergic contact dermatitis following long-term (6 years) high oral consumption of peppermint tea (Vermaat et al 2008). Moreover, the application of a transcutaneous patch (Foti et al 2003) or foot spray (Kalavala et al 2007) caused allergic contact dermatitis. However, the incidence of allergic contact dermatitis due to peppermint and its components is low considering its widespread use and seems to be more common in patients with a history of allergic reactions (Kalavala et al 2007, Vermaat et al 2008). As long as the pulegone content is kept to a minimum, peppermint oil and peppermint extract are considered to have a very good safety profile.

SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

Felodipine

Peppermint oil has been shown to increase the oral bioavailability of felodipine in animal studies (Dresser et al 2002b) — use this combination with caution.

Simvastatin

Peppermint oil has been shown to increase the oral bioavailability of simvastatin in animal studies (Dresser et al 2002b). Observe the patient and monitor drug requirements — possible beneficial interaction.

Cyclosporin

Peppermint oil has been shown to increase the oral bioavailability of cyclosporin in animal studies (Dresser et al 2002b) — avoid concurrent use, unless under medical supervision.

Drugs metabolised by CYP3A4 liver enzyme

Peppermint may increase the oral bioavailability of certain drugs by inhibition of CYP3A4-mediated drug metabolism, which has been demonstrated in vitro but not in test animals (Dresser et al 2002a, Maliakal & Wanwimolruk 2001). Although these studies seem to suggest that peppermint may modulate drug-metabolising enzymes, the clinical significance of this is unknown and requires further investigation.

CONTRAINDICATIONS AND PRECAUTIONS

Hypersensitivity to peppermint oil (Morton et al 1995)

Non-enteric-coated peppermint may be best avoided in patients with gastro-oesophageal reflux symptoms (McKay & Blumberg 2006). Avoid chewing enteric-coated capsules as it may cause heartburn (Liu et al 1997). Avoid the use of peppermint oil on the face of infants and small children. Capsules containing peppermint oil are contraindicated in biliary duct occlusion, gall bladder inflammation and severe liver damage (Blumenthal et al 2000). Similarly, caution has been urged in patients with hiatal hernia and kidney stones (McKay & Blumberg 2006).

PREGNANCY USE

Safe dosages in pregnant women have not been determined; however, external use is likely to be safe.

PRACTICE POINTS/PATIENT COUNSELLING

- Peppermint oil and/or peppermint leaf extracts can be used for IBS, dyspepsia, flatulence, intestinal colic and biliary disorders. Note, however, that peppermint oil is contraindicated in inflammation of the gall bladder and severe liver disease.
- Although enteric-coated peppermint oil capsules may prevent side effects such as reflux and allow higher doses to be used, traditional extracts of peppermint, including hydroethanolic extracts and infusions, may also be effective.
- Peppermint leaf extract combines well with chamomile, caraway, licorice, lemon balm, angelica, St Mary's thistle and the bitter candytuft (*Iberis amara*) in the treatment of functional dyspepsia (Madisch et al 2001).
- Peppermint oil can be used as an inhalation or chest rub for coughs, sinusitis and bronchitis. Commission E approved peppermint oil for internal use in the treatment of respiratory tract inflammation (Blumenthal et al 2000), and hot peppermint leaf infusion is used as a diaphoretic tea in the treatment of colds and influenza.
- Peppermint oil can be inhaled to reduce nausea and may enhance cognitive performance and tactile tasks.
- Ten per cent peppermint oil in ethanol solution can be applied externally for tension headaches and over affected areas for postherpetic neuralgia.

PATIENTS' FAQs

What will this herb do for me?

Peppermint is a safe herb for gastrointestinal disorders, including dyspepsia and IBS. It is also safe for children, particularly as a herbal tea.

When will it start to work?

Peppermint will generally have an immediate effect, with the condition continuing to improve with long-term use.

Are there any safety issues?

Concentrated peppermint oil preparations may theoretically interact with a number of different medications. It is unlikely that any interaction will occur with peppermint tea or simple liquid extracts. Avoid the use of peppermint oil on the face of infants and small children.

Perilla

HISTORICAL NOTE Perilla is an annual plant native to Eastern Asia. It was introduced to Japan from China and is now cultivated extensively in Japan, India and Korea. The seed is mainly used for its high oil content, and the leaves of *Perilla frutescens* var. *crispa* are used as a vegetable and food colouring in gourmet cooking. The salty umeboshi plum is coloured by the addition of special red perilla leaves. In China, perilla has been used to reduce the risk of food poisoning by cooking seafood with the leaf (Bensky & Gamble 1986). In recent times, certain compounds (monoterpenes) isolated from the oil are being investigated as an anticancer treatment, and the defatted seed extract is used in the treatment of allergies.

COMMON NAME
Perilla

OTHER NAMES
Beefsteak plant, Chinese basil, purple perilla, wild sesame (English common names), Ban Tulsi (Bengali), Su Zi (Mandarin), Shosi, Egoma (Japanese). Different names are used for the different parts of the perilla plant used as foods or medicines.

BOTANICAL NAME/FAMILY
Perilla frutescens (L.) Britt.

There are several botanical variants that seem to be used interchangeably: *P. frutescens* var. *crispa*, *P. frutescens* var. *japonica* (family Lamiaceae or Labiatae [mint family]).

PLANT PARTS USED
Leaf, stem and the fruit (seed) are used.

CHEMICAL COMPONENTS

As different parts of the plant are used, this section will deal with each part individually.

Raw oil

Perilla seed contains 25–51% lipids. The raw perilla oil has been used as a drying oil in paints, varnishes, linoleum, printing ink and lacquers and for protective waterproof coatings on cloth. It has also been used for cooking and as a fuel.

Refined oil

The purified oil is rich in fatty acids including palmitic acid, linoleic acid, alpha-linolenic acid, stearic acid, eicosenoic acid and arachidic acid. The omega-3 essential fatty acid, alpha-linolenic acid, comprises over 60% of the oil (Tan et al 1998).

Defatted perilla seed extract

Defatted perilla seed extract is a concentrated ethanolic extract rich in polyphenolic compounds including rosmarinic acid and rosmarinic acid methyl ester and the flavones apigenin, luteolin and chrysoeriol. Normally, flavonoids exist as glycosides in plants; however, in perilla seed extract, they occur as aglycones (free flavonoids), which have more potent activity. The defatted extract is free of perillyl ketone, perillyl aldehyde and perillyl alcohol (Oryza Co 2003).

Leaf

The leaf contains flavones, including apigenin and luteolin; flavone glycosides, anthocyanins, phenolic compounds, including rosmarinic acid, and aldehydes including perillyl aldehyde (Makino et al 2003a).

Essential oil

The volatile oil is distilled from the dried foliage of perilla. It contains perillyl aldehyde, elsholtziaketone, perillyl ketone, citral and perillene, in addition to more than 70 other compounds (Ito et al 1999). Notably, rosmarinic acid is one of the major polyphenolic ingredients of perilla leaf. Perillyl aldehyde is used as a sweetener and flavouring agent. One of the aldehyde isomers is 2000-fold sweeter than sugar and 4–8-fold sweeter than saccharin. Perillyl alcohol, prepared from perillyl aldehyde, is used in fragrances (Misra & Husain 1987). There are different chemotypes of perilla; one genotype lacks perillyl aldehyde but has perillyl ketone (Brenner 1993).

MAIN ACTIONS

The herb has several different actions, and the part of the plant used will determine which is exhibited. As such, this review includes information about which part of the herb is responsible for the activity listed. Additionally, much research has been conducted with the rosmarinic acid and luteolin components isolated from perilla.

Anti-inflammatory action

Both the refined oil and seed extract demonstrate anti-inflammatory activity in vitro.

Refined oil

The pharmacological effects of the refined oil are associated with its high level of alpha-linolenic acid, which is metabolised in the body to eicosapentaenoic acid (EPA) and docosahexaenoic acid. EPA is a precursor of the series 3 prostaglandins, the series 5 leukotrienes and the series 3 thromboxanes, which have anti-inflammatory and anti-atherogenic properties. The effects have been shown clinically, as perilla seed oil significantly suppressed the generation of leukotrienes in patients with asthma in an observational study comparing two groups of patients with asthma, one of whom received perilla oil for 4 weeks. Ventilatory parameters, such as peak expiratory flow (PEF), forced vital capacity (FVC) and forced expiratory volume (FEV_1), increased significantly after 4 weeks' dietary supplementation in the treated group (Okamoto et al 2000). In vivo dietary perilla oil has been shown to alleviate inflammation in mice via decreasing the secretion of proinflammatory cytokines (Chang et al 2008).

Seed extract

Perilla seed extract, as well as its constituents luteolin, rosmarinic acid and chrysoeriol, has been shown to inhibit 5-lipoxygenase in vitro and therefore leukotriene synthesis. Leukotrienes are associated with both allergic and inflammatory disorders, including hay fever, asthma and inflammatory bowel disorders.

Anti-allergic activity

In both in vitro and animal models of allergy, perilla preparations have demonstrated anti-allergic effects. Luteolin and rosmarinic and caffeic acids are chiefly responsible for this activity.

Seed extract

The defatted seed extract has been shown to inhibit chemically induced type IV allergy and inflammation in vivo, with the luteolin constituent exhibiting the most potent activity.

Perilla seed extract has also been shown to inhibit histamine release from mast cells in a dose-dependent manner. The effect is more potent than for isolated flavonoids including catechin, quercetin and caffeic acid. Additionally, in a case report of perilla seed extract, 150 mg/day for 2 weeks selectively inhibited the production of serum IgE in two human subjects suffering allergic symptoms including sneezing, nasal obstruction and itchy eyes (Oryza Co 2003).

Leaf

Perilla leaf extract is thought to down-regulate Th2-type cytokine production and prevent the Th1/Th2 balance from shifting towards Th2-type immune responses. A study on the effects of perilla leaf extract on cytokine production in allergic reaction in mice found that it suppressed IgE and IgG antibodies as well as IL-4, IL-5 and IL-10 (Ishihara et al 1999).

An aqueous extract of perilla leaf was shown in vitro and in vivo to inhibit local and systemic

reactions in a mast cell-mediated immediate-type allergic reaction. Plasma histamine levels and cyclic adenosine monophosphate (AMP) were reduced in a dose-dependent manner. Perilla also inhibited IgE-induced tumour necrosis factor (TNF)-alpha production (Shin et al 2000). Oral administration of a hot water extract of perilla leaf was also shown to inhibit histamine release from mast cells and reduce scratching in an animal model of dermatitis (Wakame et al 2000).

Oral administration of a perilla leaf extract inhibited the inflammatory response in an induced allergic reaction in animals. Luteolin, rosmarinic and caffeic acids were isolated and identified as active constituents. Luteolin has been shown in vivo to inhibit TNF-alpha and arachidonic acid and reduce oedema (Ueda et al 2002). In another inflammatory model, perilla dose dependently reduced the allergic response in mice by over 40%. Rosmarinic acid was identified as the main active constituent (Makino et al 2001) and has been shown to decrease the inflammatory response and increase superoxide radical scavenging in vivo (Osakabe et al 2004a). An extract of perilla leaf with high levels of rosmarinic acid decreased cytokine activity in asthma-induced rats (Sanbongi et al 2004). A perilla leaf decoction was found to suppress IgA nephropathy in genetically predisposed rats, possibly through modulation of the intestinal mucosal immune system. Perilla suppressed proteinuria, proliferation of glomerular cells, serum levels of IgA, glomerular IgA and IgG depositions in the mice. Rosmarinic acid seems to produce this effect synergistically with other constituents (Makino et al 2003b).

Antioxidant activity

A methanolic extract of roasted defatted perilla seed has been shown to exert strong antioxidant activity, and upon fractionation, luteolin was identified as one of the active antioxidant constituents (Jung et al 2001). Rosmarinic acid inhibits NO and nitric oxide synthase (iNOS) in vitro (Qiao et al 2005, Renzulli et al 2004). Aqueous extract of perilla significantly inhibits free radical production by neutrophil leucocytes (Zekonis et al 2008).

Immunostimulant

Perilla leaf extract stimulates phagocytosis in vitro and in vivo (Simoniene et al 2005). An increase in neutrophil phagocytosis was noted after 7 days but was strongest after 4 weeks of treatment. A polysaccharide extract from perilla leaf has also demonstrated phagocytic ability both in vitro and in vivo (Kwon et al 2002).

Antimicrobial activity

Perilla may help prevent dental caries and periodontal disease. Perilla seed extract has been shown to have antimicrobial activity against oral cariogenic streptococci and periodontopathic *Porphyromonas gingivalis*. The luteolin constituent showed the strongest antimicrobial effect among the phenolic compounds tested (Yamamoto & Ogawa 2002).

Hepatoprotective effects

Perilla extract and its constituent rosmarinic acid have both been shown to be hepatoprotective against lipopolysaccharide-induced liver damage in mice, possibly due to the antioxidant activity (Osakabe et al 2002).

Hypocholesterolaemic effects

Hypocholesterolaemic effects of perilla have been demonstrated in vivo. Perilla oil lowers cholesterol by suppressing hepatic beta-hydroxy-beta-methylglutaryl-CoA (HMG-CoA) reductase activity (Du et al 2003). Perilla oil also lowers plasma triacylglycerol by suppressing fatty acid synthase (Kim et al 2004) and stimulating acyl-CoA oxidase (Kim & Choi 2005) in the liver.

Perilla oil mixed with borage and evening primrose oil has been shown to reduce cholesterol in older rats (Fukushima et al 2001).

Anticancer effects

Several constituents found in perilla have demonstrated anticancer effects in vitro and in experimental cancer models. This has prompted phase I and phase II clinical testing with one key active constituent, perillyl alcohol.

Conjugated alpha-linolenic acid from perilla oil has been shown to reduce the rate of carcinogenesis in a chemically induced rat mammary cancer model (Futakuchi et al 2002). The fibrinolytic and antioxidative activities of rosmarinic acid suppress the proliferation of mesangial cells in vivo (Makino et al 2002, Osakabe et al 2004b). Animal studies have demonstrated the ability of perillyl alcohol to inhibit tumorigenesis in the mammary gland (Yuri et al 2004) and skin (Lluria-Prevatt et al 2002). The precise mechanism of action is unclear, but it is thought that compounds other than the rosmarinic acid stimulate apoptosis (Lin et al 2007). Perillyl alcohol has been shown to inhibit part of the signal transduction cascade involved in uncontrolled cell proliferation, upregulate the mannose-6-phosphate receptor and induce apoptosis (Liston et al 2003, Xu et al 2004). Perillyl alcohol has also demonstrated an ability to decrease the release of vascular endothelial growth factor from cancer cells and encourage the expression of angiopoietin-2 by endothelial cells (Loutrari et al 2004). This indicates that perilla may play a role in decreasing the vascularisation of tumours and inducing regression. The effects of perillyl alcohol and its metabolite perillic acid on the proliferation of non-small cell lung cancer cells were investigated in vivo. Both elicited dose-dependent cytotoxicity, induced cell cycle arrest and apoptosis in a dose-dependent manner (Yeruva et al 2007).

Perillyl alcohol increases the sensitivity of cancer cells in vitro to radiation treatment of prostate cancer (Rajesh & Howard 2003), glioma (Rajesh et al 2003) and certain neck and head cancers (Samaila et al 2004).

Antidepressant activity

Several different constituents within perilla leaf have demonstrated effects on behaviour in vivo, most notably antidepressant effects. Perilla demonstrated

an antidepressant-like property in animal models of depression, possibly through cell proliferation in the hippocampus (Ito et al 2008b). Rosmarinic acid and caffeic acid have demonstrated antidepressant activity in a forced swimming test in mice. The activity is thought to be via some mechanism other than the inhibition of monoamine transporters and monoamine oxidase (Takeda et al 2002a). Apigenin from perilla significantly reduced immobility in a forced swimming test in mice, an effect mediated by dopaminergic mechanisms (Nakazawa et al 2003). Inhalation of L-perillaldehyde, a major component in the essential oil, shows antidepressant-like activity in mice through the olfactory nervous function (Ito et al 2008a).

Rosmarinic acid and caffeic acid have been shown to decrease the duration of the defensive freezing behaviour caused by fear and stress in animals (Takeda et al 2002b).

OTHER ACTIONS

Perilla oil has been shown to reduce the excessive growth of visceral adipose tissue in rats by down-regulating adipocyte differentiation in animals (Okuno et al 1997). This has direct relevance to obesity, as a high-fat diet not only accelerates the filling process of preexisting preadipocytes but also stimulates the proliferation of adipose precursor cells. Adipocyte differentiation, from adipoblasts to adipocytes, is a key factor underlying obesity.

A glycoprotein isolated from perilla oil has been shown to inhibit an early stage of HIV-1 replication without blocking viral adsorption in vitro (Kawahata et al 2002, Yamasaki et al 1998).

Perilla aldehyde has demonstrated vasodilatory activity in isolated rat aorta and appears to work by blocking Ca^{2+} channels (Takagi et al 2005). The clinical significance of this is currently unknown.

CLINICAL USE

The form most commonly used at the moment is the extract of defatted perilla seed; however, this review will also include information regarding other forms.

Cancer

Phase I clinical trials have shown a favourable toxicity profile, and preliminary data have indicated some chemotherapeutic efficacy in advanced cancers. In vitro studies suggest that perillyl alcohol inhibits the expression and function of androgen receptors in human prostate cancer cell line, suggesting that perillyl alcohol could be useful for intervention of prostate cancer (Chung et al 2006). Another in-vitro study of a combination of perillyl alcohol with a virally delivered therapeutic cytokine shows promise for both preventing and treating human pancreatic cancer without toxic effects (Lebedeva et al 2008).

However, perillyl alcohol (1200 mg/m^2 four times daily) failed to extend the time-to-progression in three phase II studies in patients with advanced ovarian carcinoma (Bailey et al 2002), prostate cancer (Liu et al 2003) and colorectal cancer. All trials were very small and had to contend with high dropout rates due to intolerability of the medicine. Despite encouraging preclinical results, perilla does not appear to zbe an effective treatment for advanced cancer.

Topical perillyl alcohol inhibits ultraviolet B-induced skin carcinogenesis in vivo so has been tested clinically for activity. A 1-month, double-blind, phase 1 trial of topically administered perillyl alcohol cream was trialled in 25 human subjects. They were monitored for toxicity and underwent histopathological evaluation. The topical cream was well tolerated. No serious cutaneous toxicities, systemic toxicities or histopathological abnormalities were observed. However, there was no significant difference between lesions appearing on the treated forearm versus the placebo-treated forearm (Stratton et al 2008).

Allergy

Based on traditional use, in vitro and in vivo studies and human trials, perilla leaf and defatted seed extracts are used for allergic respiratory disorders including hay fever, asthma and sinusitis. The refined oil may also help allergic and inflammatory respiratory conditions by regulating the arachidonic acid metabolism pathways and suppressing leukotriene generation.

A double-blind, randomised, placebo-controlled clinical trial showed a significant reduction in symptoms such as watery eyes, itchy eyes and itchy nose in 29 patients with seasonal allergic rhinoconjunctivitis, taking 50 or 200 mg of rosmarinic acid-enriched perilla for 21 days (Takano et al 2004). Responder rates were 55.6 and 70%, respectively. A drastic reduction in the number of neutrophils and eosinophils in nasal fluid was also demonstrated.

In an open clinical trial, 20 human subjects suffering allergic symptoms, including sneezing, nasal obstruction and itchy eyes and skin, were treated with 100–150 mg perilla seed extract daily (higher dose for persons over 60 kg) for 2 weeks. The subjects themselves evaluated changes in the severity of symptoms. Significant improvement was noted in 80% of the subjects for nasal obstructive symptoms, 40% reported a significant improvement in sneezing and half reported a significant reduction of itchy eyes (Oryza Co 2003).

A systematic review of double-blind randomised trials evaluating various herbal medicines in patients with allergic rhinitis concluded that perilla (part used not specified) showed promising results (Guo et al 2007).

Perilla leaf extract cream

Open studies of more than 100 children with atopic dermatitis found that perilla leaf extract cream improved symptoms in 80% of cases after 3 months' treatment (Yu & Kosuna 1997). Another open study with 20 allergic patients, using perilla leaf cream topically and perilla leaf extract orally, showed a general improvement in 90% of the patients after 2 months, with 30% reporting significant improvements (Yu et al 1997).

Dental caries and periodontal disease

Perilla seed extract inhibits the growth of cariogenic and inflammatory microorganisms including oral streptococci and *Porphyromonas gingivalis*

Clinical note — Perilla and traditional medicine systems

Perilla is an important ingredient of several Traditional Chinese Medicine (TCM) formulas. Perilla leaf is a key ingredient in Saiboku-to, a traditional Chinese formulation used in the treatment of type 1 hypersensitivity disorders including asthma (Nishiyori et al 1985). Saiboku-to contains *Bupleurum falcatum*, *Pinellia ternata*, *Poria cocos*, *Scutellaria baicalensis*, *Magnolia officinalis*, *Zizyphus spinosa*, *Panax ginseng*, *Glycyrrhizae uralensis*, *Zingiber officinale* and perilla. Another TCM formula containing perilla, Sam So Eum, is used to treat asthma and has been shown in an animal model to decrease airway hyperresponsiveness by restoring the immunomodulating cytokines. The anti-inflammatory effects of this formula are similar in effectiveness to prednisolone (Cho et al 2008). Perilla is also a component of the Banxia Houpu Decoction used for depression. It contains *Pinellia ternata*, *Poria cocos*, *Magnolia officinalis*, *Perilla frutescens and Zingiber officinale* (Luo et al 2000). Perilla leaf has been prescribed as one of the component herbs in certain Kampo (Japanese herbal) medicines that are used clinically for the improvement of depressive mood. These formulae demonstrate antidepressant-like effect in mice models through suppressing the hyperactivity of the hypothalamic-pituitary-adrenal (HPA) axis (Ito et al 2006).

(Yamamoto & Ogawa 2002). Perilla seed extract also reduces inflammation through inhibition of leucocyte production and radical scavenging activity. As such, application of the extract in the oral cavity is used to reduce dental caries and pericoronitis.

OTHER USES

Refined perilla oil is a good source of n-3 series alpha-linolenic acid.

DOSAGE RANGE

- Perilla leaf: extract equivalent to 4–9 g/day (Bensky & Gamble 1986).
- Refined perilla oil: 1000 mg capsules taken three to six times daily.
- Perilla seed extract (containing a minimum of 3.0% polyphenols): 100–150 mg/day (Oryza Co 2003).
- External use (dental caries and periodontal disease): 80–160 mg defatted perilla seed daily delivered directly into the oral cavity in the form of toothpaste, chewing gum or mouth rinse.

ADVERSE REACTIONS

Defatted perilla seed extract has very low toxicity. After administering 2000 mg/kg to mice for 2 weeks, no toxic effects were observed (LD_{50} for mice is therefore more than 2000 mg/kg). Dosage of 7.0 g/kg for 2 weeks did not produce any toxic effects in humans.

In Japan, 20–50% of long-term workers in the perilla industry develop dermatitis on their hands due to contact with perillyl aldehyde (Brenner 1993).

A 13-week subchronic oral toxicity study of perilla leaf extracts in drinking water did not show any acute toxicity. There were no treatment-related changes in body weight gain or in haematological or blood biochemistry values. Nor were there any treatment-related histopathological changes observed in the highest dose group (Yun et al 1999).

There has been a report of lipoid pneumonia in a 57-year-old man who had a history of ingesting green perilla oil, and there was also residual neurologic deficit of cerebral infarction with right hemiparesis (Kwang et al 1999).

Phase I and II clinical trials of perillyl alcohol for certain cancers have shown that gastrointestinal side effects and fatigue are the most common adverse reactions (Azzoli et al 2003, Bailey et al 2002, 2004, Liu et al 2003, Meadows et al 2002). Gastrointestinal effects are usually mild and include nausea, vomiting, bloating and belching. Doses were usually between 1200 and 1600 mg/m^2 four times daily.

The refined perilla oil is clear golden yellow. It is fully refined (neutralised, bleached and deodorised) and should be free of perillyl ketone, which is a potent lung toxin that causes increased microvascular permeability and pulmonary oedema in grazing animals (Waters et al 1993).

SIGNIFICANT INTERACTIONS

Controlled studies are not available, so interactions are based on evidence of activity and are largely theoretical and speculative.

Antihistamine agents

Theoretical additive effect is possible. Patients taking perilla concurrently with antihistaminic should be observed and drug doses modified if required.

Contraindications and precautions

None reported for perilla seed extract or refined oil; however, perilla leaf extract is contraindicated in diarrhoea (Bensky & Gamble 1986).

PRACTICE POINTS/PATIENT COUNSELLING

- Perilla exhibits anti-inflammatory, anti-allergic, antioxidant and anticariogenic activity. Preliminary evidence also suggests hepatoprotective and behavioural effects.
- Perilla leaf and defatted seed extracts are specifically used for allergic respiratory disorders including hay fever, asthma and sinusitis.
- Perilla leaf and defatted seed extract may down-regulate Th2-type cytokine production and prevent the Th1/Th2 balance from shifting towards Th2-type immune responses that may be associated with a range of allergic reactions and autoimmune disorders.
- Refined perilla oil is a good source of n-3 series alpha-linolenic acid, and extracts should be free of perillyl ketones and aldehydes.

PREGNANCY USE

Insufficient information is available to determine the safety of perilla during pregnancy.

PATIENTS' FAQs

What can this herb do for me?

Perilla is used in the treatment of allergic respiratory conditions, such as hay fever, asthma and sinusitis. Preliminary evidence suggests that it may be beneficial; however, more rigorous studies are still required to confirm effectiveness.

When will it start to work?

Relief of symptoms should be noticed within the first week, although it may take a couple of weeks to show a significant effect. For hay fever, it would be beneficial to start taking perilla at least 1 month before the onset of the hay fever season.

Are there any safety issues?

Perilla is very well tolerated and nontoxic. It can be used long term if indicated.

Policosanol

BACKGROUND AND RELEVANT PHARMACOKINETICS

Policosanol is isolated from the waxes of plants such as sugar cane. The main component, octacosanol, has variable absorption from the small intestine and is chiefly metabolised by the liver and excreted in the faeces.

CHEMICAL COMPONENTS

Policosanol is a mixture of long-chain primary aliphatic alcohols (Arruzazabala et al 1993a). The alcohols have a chain length ranging from 24–34 carbons and the major components of the mixture are octacosanol (60–70%, w/w), triacosanol (10–15%, w/w) and hexacosanol (4–10%, w/w) (Francini-Pesenti et al in press). Octacosanol is regarded as the main active constituent.

MAIN ACTIONS

Lipid lowering

Cuban sugar cane policosanol (CSP), derived from the waxy coating of stems and leaves of sugar cane and other plant materials, has been shown to exert significant lipid lowering effects in animals and humans in numerous studies conducted by a single laboratory and using a CSP product manufactured by Dalmer laboratories (La Havana, Cuba). Tests investigating CSP with experimental models including rats, rabbits, dogs and monkeys have demonstrated reductions in circulating total cholesterol (TC) levels consistently greater than 13% (Kassis et al 2007). Similarly, human studies using CSP have shown significant reductions in total cholesterol and LDL-cholesterol.

Many of these previous findings must now be questioned because there has been a plethora of negative clinical and experimental studies published since 2006 which have been unable to detect lipid lowering activity for CSP and other policosanol preparations.

Reduces oxidation of LDL-cholesterol

This has been demonstrated in vitro at an equivalent dose of 5 and 10 mg/day (Menendez et al 2000).

Reduces platelet aggregation

This has been confirmed in animal models and randomised double-blind studies, with effects starting at 10 mg/day (Castano et al 1999a, Arruzazabala

et al 1993b, 2002). One clinical study found that a dose of 20 mg/day policosanol produces the same inhibitory effects on platelet aggregation as 100 mg aspirin daily (Arruzazabala et al 1997). A higher dose of 40 mg policosanol does not appear to produce any further antiplatelet effects according to another double-blind study (Arruzazabala et al 2002). Thromboxane, but not prostacyclin, generation induced by collagen is also inhibited by policosanol in clinical studies (Carbajal et al 1998a).

OTHER ACTIONS

Endothelial protection

Oral administration of policosanol to spontaneously hypertensive rats resulted in a significant reduction in circulating endothelial cells compared with controls. Moreover, comparison between groups revealed a lower frequency of aortic lesions in policosanol-treated animals than in untreated animals (Noa et al 1997).

Antihypertensive effects at very high doses

Tests in animal models have identified enhancement of propranolol-induced hypotensive effects with pretreatment at 200 mg/kg policosanol (Molina et al 1999), which is an extremely high dose and clinically irrelevant in humans.

Reduces atherosclerotic lesion development

According to one animal study, most policosanol-treated animals did not develop atherosclerotic lesions compared with an untreated group, and the thickness of fatty streaks that did develop with treatment had fewer foam cell layers than in controls (Arruzazabala et al 2000).

CLINICAL USE

Policosanol is most often used in the management of hyperlipidaemia and is sold as a lipid lowering agent in over 40 countries world-wide (Francini-Pesenti et al in press).

Hyperlipidaemia

Multiple clinical trials conducted with Cuban sugar cane policosanol (CSP), manufactured by Dalmer laboratories (La Havana, Cuba), support its use and indicate significant lipid lowering activity. Studies conducted by other research groups outside Cuba have not been able to reproduce the results obtained in the original studies, casting doubt over the product's lipid lowering activity. This review will therefore include information from all research parties, allowing the readers to make their own judgment as to whether policosanol is an effective treatment for hyperlipidemia.

Numerous randomised, double-blind clinical trials conducted prior to 2006 demonstrated significant cholesterol-lowering effects of oral policosanol (Castano et al 2001b, Mas et al 1999, Menendez et al 2000, Pons et al 1994, Torres et al 1995). Several previous studies conducted with postmenopausal women have confirmed efficacy in this population (Castano et al 2000, Mas et al 1999, Menendez et al 2000, Mirkin et al 2001, Pons et al 1994, Torres et al 1995). Overall, these results show that a daily dose of 5 mg policosanol may:

- reduce LDL-cholesterol by 11–18%
- reduce total cholesterol by 8–15%
- increase HDL by 8–15%,

whereas a higher dose of 20 mg policosanol daily can:

- reduce LDL-cholesterol by 31%
- reduce total cholesterol by 23%
- increase HDL by 27%.

Recent controversy

It is important to note that previous studies had used the same specific policosanol product and research had been conducted almost entirely by the same research group in Cuba and involved Hispanic patients. In 2006 the evidence base shifted dramatically because five negative clinical studies were published which were conducted by different research teams around the world, using either Cuban or non-Cuban policosanol products.

In Germany, Berthold et al conducted a 12-week randomised study of 143 Caucasian subjects with hypercholesterolaemia or combined hyperlipidaemia. The multi-centre study used CSP at doses of 10, 20, 40 and 80 mg/day. In contrast to previous studies, policosanol failed to significantly reduce LDL-cholesterol, total cholesterol, HDL-cholesterol, triglycerides and other lipid parameters at all test doses (Berthold et al 2006). In a US double-blind, placebo controlled trial of 40 healthy adults with mild hypercholesterolaemia, conducted by Dulin et al (2006), subjects were assigned to receive oral policosanol 20 mg or placebo once daily for 8 weeks. No significant changes were seen for LDL-cholesterol, total cholesterol, HDL-cholesterol, triacylglycerol, C-reactive protein and nuclear magnetic resonance spectroscopy-determined profiles. Also in the US, Cubeddu et al (2006) divided subjects with LDL-cholesterol (LDL-C) levels from 140 to 189 mg/dL into four groups and compared policosanol 20 mg to atorvastatin 10 mg, combination therapy or placebo for 12 weeks (Cubeddu et al 2006). In total, 99 patients took part and groups were well matched at baseline. Yet again, policosanol failed to have a significant effect on any lipid parameter and produced no additional lipid lowering effects when added to atorvastatin. In Canada, Kassis & Jones (2006) compared policosanol 10 mg/day to placebo in 21 people over a period of 28 days. The double-blind, crossover study also failed to find significant changes to plasma lipid levels for total, LDL-C, HDL-C and triacylglycerol concentrations with policosanol treatment. In South Africa, Greyling et al (2006) conducted a double-blind study involving 19 hypercholesterolaemic and familial hypercholesterolaemic subjects who received either policosanol 20 mg/day or placebo for 12 weeks. After a 4-week wash-out period, the interventions were crossed over and treatment recommenced. No significant differences in total cholesterol and LDL-C from baseline to end or between policosanol and placebo

Clinical note — Policosanol controversy

It is currently uncertain whether policosanol has significant lipid lowering activity due to the recent spate of negative clinical trials which have failed to confirm earlier positive results. Several theories may explain the discrepancy such as differences in the purity and composition of different policosanol products, insufficient test time-frames, differences between test subjects and, of course, researcher bias.

Researchers external to the original Cuban research groups have begun testing these different theories to uncover the answer. Theories proposing differences in octacosanol content have been discounted as the various policosanol products tested externally have contained similar concentrations to the original Cuban blend. Another suggestion is that products may have differed in minor alcohol content, explaining the disparate results. To test this theory, Cuban policosanol has been directly compared to other policosanol products in various animal models. Using a hamster model, Kassis et al compared Dalmer Cuban policosanol to an alternative Degussa policosanol mixture and found that neither treatment had a significant effect on lipids (Kassis et al 2007). A second research team headed by Marinangeli also compared Cuban policosanol to another product with a similar amount of octacosanol and found no differences between them for tissue, plasma and faecal policosanol levels in an animal model (Marinangeli et al 2007). In regards to time frames, Cuban clinical studies indicate that lipid lowering activity can be observed by 4 weeks of treatment and reaches a maximal effect between 6 and 8 weeks. Studies conducted by Berthold et al (2006), Greyling et al (2006) and Cubeddu et al (2006) lasted 12 weeks and still found no significant activity so this theory can also be discounted. Finally, genetic differences between test subjects and differences in dietary habits could account for the varied responses between test subjects, however this appears unlikely.

were seen in the hypercholesterolaemic or familial hypercholesterolaemic groups.

Since 2006, the negative evidence has continued to accumulate as studies using animal models and clinical trials consistently fail to find significant lipid lowering activity for either CSP or its other forms (Francini-Pesenti et al in press, Kassis et al 2007, Marinangeli et al 2007, Kassis 2008, Kassis & Jones 2008).

Studies of type 2 diabetes

Studies conducted prior to 2006 indicate that policosanol has proven effects in dyslipidaemia secondary to type 2 diabetes mellitus (Crespo et al 1999, Torres et al 1995). Until these results can be confirmed by other research groups, these results remain uncertain.

Comparative trials with HMG-CoA reductase inhibitor

Whilst several randomised, double-blind studies comparing the effects of policosanol with standard hyperlipidaemic treatment (with statin drugs such as simvastatin and pravastatin) have produced favourable results (Alcocer et al 1999, Castano et al 1999b, Crespo et al 1999, Prat et al 1999, Torres et al 1995, Castano et al 2003b) it now appears unlikely that policosanol has lipid lowering effects comparable to statin drugs.

Concurrent use with omega-3 essential fatty acids

Due to the favourable effects of omega-3 fatty acids (FAs) in cardiovascular disease, in practice clinicians have recommended policosanol together with fish-oil supplements. According to an 8-week, double-blind, randomised study, the combination effectively reduced total cholesterol, LDL-C and triglycerides and increased HDL-C (Castano et al 2005). The study of 90 patients with type II hypercholesterolaemia found that when omega-3 FAs (2 g/day) were combined with policosanol (10 mg/day), there was a significant decrease in total cholesterol (15.3%) and triglycerides (14.7%), and a significant increase in HDL-C (15.5%). These results require substantiation by other research groups before they can be confirmed.

Concurrent use with beta-blockers

A 3-year randomised study of 205 older hypercholesterolaemic patients taking beta-blockers to showed that after 1 year of therapy, policosanol significantly reduced LDL-C (20.9%), total cholesterol (19.3%) and triglycerides (25.7%) and increased HDL-C levels (4.1%), effects that lasted for the duration of the study (Castano et al 2004a). The frequency of mild, moderate or severe adverse events was lower in the policosanol group than in the placebo group; however, an additional reduction in SBP and DBP was observed in the policosanol patients compared with those in the placebo group. Until these results can be confirmed by other research groups, these results remain uncertain.

Wheat-germ-derived policosanol

No beneficial effects on blood lipid profiles were observed in a double-blind, randomised study of 58 subjects with normal to mildly elevated plasma cholesterol who were given 20 mg wheat-germ policosanol in a short 4-week study (Lin et al 2004).

Intermittent claudication

Policosanol treatment for intermittent claudication has produced encouraging results in several randomised studies (Castano et al 1999b, 2001a, 2003a). Policosanol 10 mg/day taken for 6 months significantly increased initial claudication distance by approximately 70 metres and absolute claudication by approximately 140 metres in one double-blind study, whereas placebo produced no changes (Castano et al 1999b). A single-blind study using 20 mg policosanol daily showed significant improvements

after 6 months' treatment, which further increased after 12 months (Castano et al 2001b). In both studies patients in the policosanol group reported improvements in lower limb symptoms that were greater than those in the placebo group.

More recently, policosanol (10 mg twice daily) was shown to be as effective as ticlopidine (250 mg twice daily) for improving walking distances of claudicant patients (Castano et al 2004b). In the 20-week double-blind, randomised study of 28 subjects, policosanol significantly increased mean values of initial and absolute claudication distances from 162.1 to 273.2 metres and from 255.8 to 401.0 metres, respectively, which was not significantly different to ticlopidine. Both treatments were well tolerated.

In 2008, a randomised, double-blind study comparing policosanol (10 mg/day) to aspirin (100 mg/day) was published showing that policosanol modestly but significantly increased the initial and absolute claudication walking distances whereas no change occurred with aspirin (Illnait et al 2008). The study involved 39 volunteers and treatment lasted for 10 weeks.

Until these results can be confirmed by other research groups, these results remain uncertain.

OTHER USES

Preexisting coronary heart disease (CHD)

A randomised double-blind study of 45 subjects with documented CHD found that a dose of 10 mg policosanol daily increased maximum oxygen uptake and exercise ECG responses. The effects were further enhanced by co-administration of 125 mg aspirin (Stusser et al 1998).

Cerebrovascular disease

In two different experimental models policosanol had anti-ischaemic activity when administered after induction of cerebral ischaemia, suggesting a possible therapeutic effect in CVD (Molina et al 1999).

DOSAGE RANGE

The doses tested in clinical trials range from 5–20 mg/day.

More specific doses

- Hypercholesterolaemia: 5–20 mg/day (uncertain efficacy).
- Intermittent claudication: 10–20 mg/day — 3 months' continual use may be required before effects are observed.
- Platelet inhibition: 10 mg/day.

Policosanol is usually taken after the evening meal.

TOXICITY

Studies using several animal models have confirmed no carcinogenic effects and no signs of toxicity at doses as high as 500 mg/kg (Aleman et al 1994a, 1994b). This dose is hundreds of times greater than the maximal recommended therapeutic dose (20 mg/day), thereby indicating an excellent safety profile (Mesa et al 1994).

ADVERSE REACTIONS

A pharmacovigilance study of 2252 subjects aged 60 or more years with coronary, cerebrovascular and peripheral artery disease and treated with policosanol (5, 10 or 20 mg/day) at seven major medical centres found that long-term tolerability of policosanol in elderly patients at high vascular risk was very good (Fernandez et al 2004).

SIGNIFICANT INTERACTIONS

Aspirin

Increased antiplatelet effects may develop — patients taking aspirin and policosanol concurrently should be observed for increased bleeding or bruising.

Warfarin

Current evidence suggests that there is no interaction between policosanol and warfarin. One clinical study confirmed that the addition of policosanol to warfarin therapy does not enhance the prolongation of the bleeding time induced by warfarin alone (Carbajal et al 1998b). Caution with doses > 10 mg/day.

CONTRAINDICATIONS AND PRECAUTIONS

Suspend use of high doses 1 week before major surgery.

PREGNANCY USE

Safety has been investigated in animal tests with no evidence of teratogenicity or any other embryonal toxicity (Rodriguez & Garcia 1994, 1998, Rodriguez et al 1997).

PATIENTS' FAQs

What can this supplement do for me?

It is uncertain whether policosanol can significantly lower cholesterol levels. Early studies suggested this effect is as strong as conventional cholesterol-lowering medications however more recent studies have found no effect. It also has some blood-thinning activity, may be effective in intermittent claudication and can increase total walking distance.

When will it start to work?

Early studies suggest maximal lipid lowering effects are seen after 6-8 weeks of continuous use however new evidence casts doubt over its efficacy.

Are there any safety issues?

Policosanol has a wide safety margin and is well tolerated.

PRACTICE POINTS/PATIENT COUNSELLING

- It is uncertain whether policosanol can still be considered an efficacious lipid-lowering treatment because of a recent spate of negative studies showing no significant effect.
- It is a potentially useful treatment in claudication however more research is required to confirm its effects.
- Policosanol has significant platelet aggregation inhibitor activity.
- Safety studies indicate that it is well tolerated and has a wide safety margin.

Prebiotics

HISTORICAL NOTE Gibson & Roberfroid (1995) introduced the concept of prebiotic as 'a non-digestible food ingredient that beneficially affects the host by selectively stimulating the growth and/or activity of one or a limited number of bacteria in the colon and thus improves health'. This concept has been further developed to define prebiotics as 'selectively fermented ingredients that allow specific changes, both in the composition and/or activity of the gastrointestinal microflora that confers benefits upon host wellbeing and health'.

BACKGROUND AND RELEVANT PHARMACOKINETICS

Numerous components appear to have prebiotic characteristics, but some will not be classified as prebiotics because they may not meet all the criteria i.e. not metabolised (hydrolysed or absorbed) in the upper gastrointestinal tract, demonstrates selective fermentation by one or a limited number of potentially beneficial intestinal bacteria, and change the colonic microflora to a healthier composition (Gibson & Roberfroid 1995, Roberfroid 2007). To date, the most well-known prebiotics are inulin, lactulose, fructo-oligosaccharides (FOS) and galacto-oligosaccharides (GOS) (Roberfroid 2007).

One of the key characteristics of prebiotics is to stimulate the selective growth of intestinal microorganisms and, in particular, the growth of lactobacilli and bifidobacteria.

Studies have demonstrated that the intestinal microflora of breastfed infants is characterised by high levels of bifidobacteria and lactic acid bacteria because oligosaccharides occur naturally in breast milk. Formula-fed infants were found to have more bacteroides, clostridia and enterobacteriaceae and lower levels of the beneficial microorganisms (Coppa et al 2006).

Bifidobacteria are well-known defences against pathogenic bacteria and are significant for promoting gut health (Cummings & Macfarlane 2002, Brunser et al 2006, Gibson 1998, Gibson & Roberfroid 1995). In addition to stabilising the gut microflora, prebiotics may have a role in allergy; reports indicate that infants with allergy had lower levels of lactobacilli and bifidobacteria (Bjorksten et al 2001) and feeding prebiotics was able to rectify this. Increasingly, prebiotics have been added to infant milk formulas in order to simulate the composition of human breast milk prebiotic oligosaccharides.

In recent years, there has been a focus on using multiple prebiotics together rather than a single component; combinations of long-chain FOS and short-chain GOS have been utilised mainly because different gastrointestinal microorganisms may require different substrates for optimal growth.

In both adults and the young, prebiotics are reported to have other health-promoting properties and they may have a role in the management of a number of diseases and conditions. Altered gastrointestinal microflora and abnormal colonic fermentation is also noted in some conditions such as inflammatory bowel disease (IBD) and irritable bowel syndrome (IBS) (King et al 1998); treatment with prebiotics or synbiotics may normalise the altered microflora.

Prebiotics as indigestible components are known to have laxative properties and are used as bulking agents for gastrointestinal health; the end products of the prebiotic fermentation in the colon are short-chain fatty acids (SCFAs), which have direct effects on the intestinal cells and stimulate intestinal peristalsis (Gibson 1999, 1998, Gibson & Roberfroid 1995, Gibson et al 1995).

Both lactobacilli and bifidobacteria species in the colon have important roles in immune stimulation and prevention of infection and diarrhoea (Gorbach et al 1987, Macfarlane et al 2006, Saavedra et al 1994). Some bifidobacteria and lactobacillus species may have antimutagenic and antitumour properties; prebiotics such as inulin appear to inhibit colonic cancer cell growth (Pool-Zobel & Sauer 2007).

The anti-inflammatory characteristics do not extend to all prebiotics, as some prebiotics have been reported to have adverse effects; in particular, intake of FOS has been reported to promote bacterial translocation and increase mucosal irritation in some animal studies (Bovee-Oudenhoven et al 2003).

CHEMICAL COMPONENTS

Prebiotics are principally oligosaccharides of which there are various types: oligofructose, inulins, isomalto-oligosaccharides, lactosucrose, lactulose, pyrodextrins, xylo-oligosaccharides.

Inulins are multiple fructose units and inulin degradation results in oligofructose. Oligosaccharides occur naturally in breast milk. Fructans are linear or branched fructose polymers and the GOS are synthesised from lactose by the action of beta-galactosidase. FOS are the inulin-type fructans

Clinical note — The hygiene hypothesis

The intestinal microflora is crucial for the development of the immune system (Ouwehand et al 2002) and the 'hygiene theory' suggests that exposure to microorganisms is required for this. The consumption of foods containing microorganisms for health-promoting properties has a long history. Probiotics are microorganisms that can 'beneficially affect the host physiology by modulating mucosal and systemic immunity, as well as improving nutritional and microbial balance of the intestinal tract' (Gibson & Roberfroid 1995, Salminen et al 1998).

Clinical note — Synbiotics
Synbiotics are a combination of both prebiotic(s) and probiotic(s); the selection of both of these constituents is based on the premise that they will work in synergy (Bengmark 2005). A combination of *Lactobacillus paracasei* and FOS results in increased lactobacillus and bifidobacteria and decreased clostridium and enterobacterium. In recent years, there has been a trend to increasingly use synbiotics for a synergistic health promoting effect, but this also makes it difficult to evaluate the individual effects of each component.

that can be readily obtained from plant sources. Both GOS and FOS are widely used in the food industry (Yang & Silva 1995).

FOOD SOURCES

Low levels of prebiotics can be found in artichoke, asparagus, bananas, chicory, garlic, leek, onions and wheat. Inulin and oligofructose occur naturally in food. Commercially produced prebiotics are extracted from chicory roots or synthesised from sucrose and are used widely in the food industry. Dietary intake of prebiotics is variable, with the intake for Americans being in the range 1–4 g/day and on average a higher intake among Europeans who consume 3–10 g/day (Delzenne 2003).

DEFICIENCY SIGNS AND SYMPTOMS

Clear deficiency signs are difficult to establish because the symptoms may vary enormously. Local signs and symptoms of disruption of the intestinal microflora leading to an imbalance (intestinal dysbiosis) include bloating, flatulence, abdominal pain, diarrhoea and/or constipation and fungal overgrowth (such as *Candida*). An imbalance of gastrointestinal microflora can be caused by the use of antibiotics, and chronic diarrhoea or constipation. Administration of prebiotics, probiotics or synbiotics is used as a means of restoring this microflora imbalance.

MAIN ACTIONS

In recent years, there has been a focus on the utility of prebiotics, but at present the exact mechanisms of their action remain unclear although there are a number of proposals.

Stimulation of beneficial bacteria

Many animal and human studies have demonstrated that prebiotics modulate the gut microflora by increasing bifidobacteria and lactobacilli levels (Bouhnik et al 1997, Gibson & Wang 1994, Langlands et al 2004).

Prebiotics are fermented by microflora in the proximal colon resulting in the production of short-chain fatty acids (acetic, propionic and butyrate acids) and gas (CO_2 and H_2). Consequently, the lower intraluminal pH inhibits the growth of *Bacteroides* spp and increases Lactobacilli and Bifidobacteria (Walker et al 2005). As a result of prebiotics stimulating the growth of beneficial bacteria, these microorganisms secrete antimicrobial compounds and can inhibit colonisation of the pathogenic bacteria and prevent their adherence to the intestinal epithelium (Shoaf-Sweeney & Hutkins 2009). The adherence can be also limited as a result of the oligosaccharide's terminal sugars interfering with the receptors on the pathogenic bacteria (Hopkins & Macfarlane 2003, Zopf & Roth 1996); reduced adherence of enteropathogenic *E. coli* in HeP and $CaCO_2$ cells has been noted with GOS (Shoaf et al 2006).

Immunomodulation

The mechanisms whereby prebiotics have immunomodulatory effects (modulate cytokine and antibody production) are largely unknown and the proposed mechanisms include beneficial changes in the intestinal microflora, increased production of both mucin and short-chain fatty acids (SCFAs). There may also be changes in the gut-associated lymphoid tissues (GALT) as a result of prebiotic fermentation in the colon (Forchielli & Walker 2005). The SCFAs are beneficial to the host as an energy source and enhance mucosal integrity with increased production of mucin, binding to receptors on immune cells within gut lymphoid-associated tissue (GALT) and limiting translocation; mucin may limit bacterial translocation. There is little information about the effects of prebiotics on mucin production but an animal study noted increased mucin production associated with inulin treatment (Fontaine et al 1996).

Both prebiotics and probiotics are reported to have beneficial effects in reducing the effects of colitis by altering the gastrointestinal microflora due to stimulating growth of the protective bacteria and reducing colonisation with potentially hazardous bacteria (Sartor 2004). Prebiotics (mainly inulin and FOS) may also ameliorate inflammation as a result of reducing the activity of proinflammatory transcription factors (e.g. NF-κB), and by the increased production of SCFAs (Cavin et al 2005, Holma et al 2002, Kinoshita et al 2002, Millard et al 2002). Animal studies show conflicting findings with some reporting less inflammation (Cherbut et al 2003) and others have reported that there is no protection from FOS in rat models of colitis (Moreau et al 2003). In recent years, some human studies have been undertaken and mixed results are reported. Butyrate is a major source of energy for colonocytes, and in vitro studies indicate that butyrate has anti-inflammatory effects (Saemann et al 2000, Segain et al 2000); butyrate and acetate enhance mucin secretion.

Cancer prevention

Various in vitro and animal studies have been conducted to investigate the role of prebiotics and synbiotics for their anticancer effects, but there are only a limited number of studies in humans (Pool-Zobel & Sauer 2007). Animal studies have shown that prebiotic treatment is beneficial in reducing precancerous aberrant crypt foci and the effects

are more pronounced with synbiotics. Rowland et al (1998) reported that the effect is enhanced with synbiotics such as inulin + *B. longum* in their study of azoxymethane-induced aberrant crypt foci in rats. Oligofructose-enriched inulin plus *Lactobacillus rhamnosus* and *Bifidobacterium lactis* treatment prevented azoxymethane-induced suppression of natural killer (NK) cell activity in Peyer's patches (Roller et al 2004) and similarly a study (Le Leu et al 2005) demonstrated increased apoptotic response with resistant starch + *B. lactis* treatment.

OTHER ACTIONS

Mineral metabolism

Animal studies have indicated that prebiotics such as inulin and oligofructose can affect calcium bioavailabilty and increase calcium absorption. A number of mechanisms have been proposed for this action, including the increased production of SCFAs, which increase the solubility of minerals and also facilitates the colonic absorption of calcium and magnesium (Demigne et al 2008). Human studies have mostly investigated small numbers of participants and have produced mixed findings (Scholz-Ahrens et al 2007).

CLINICAL USE

Irritable bowel syndrome (IBS)

A multicentre, prospective, randomised, double-blind, placebo-controlled study by Olesen & Gudmand-Hoyer (2000) did not find benefits for the use of FOS in the treatment of IBS, similar to the findings of Hunter et al (1999) who utilised oligofructose in their double crossover study investigating IBS. In contrast, a study with a dietary mixture containing a number of components, including inulin plus *Lactobacillius acidophilus*, *Lactobacillius sporogenes* and *Streptococcus thermophilius* was given to one group of patients with IBS (n = 37) over a 5–7 month period and the control group (n = 28) received usual care; the supplement treatment resulted in significant improvements in abdominal pain, distension and constipation (Astengiano et al 2006).

Inflammatory bowel disease (IBD)

In a study of patients with active IBD, 14 patients presenting ulcerative colitis (UC) and 17 patients presenting Crohn's disease (CD) received either standard medication treatment or the medications with an additional 10 g/day lactulose dose for 4 months; at the end of the study there were no differences in the clinical or endoscopic score, although the UC group receiving the lactulose treatment reported an improved quality of life compared to the control group (P = 0.04) (Hafer et al 2007).

Crohn's disease (CD)

At present, the role of prebiotics in the management of CD remains unknown due to a limited number of studies.

A small open-label study of 10 patients with active ileo-colonic Crohn's disease, who were treated with a combination of prebiotics (15 g/day FOS) reported a significant reduction in disease activity scores and inflammation with an increase in IL-10-positive dendritic cells and toll-like receptor 2 and toll-like receptor 4 expression; it is noteworthy that patients entering remission had increased mucosal-associated bifidobacteria (Lindsay et al 2006).

However, a randomised controlled trial of 30 patients with CD postoperative ileocaecal resection, who were treated with Synbiotic 2000, a combination of four prebiotic components + probiotic mixture of four lactic acid strains (*Pediacoccus pentoseceus*, *Lactobacillus raffinolactis*, *Lactobacillus paracasei susp paracasei* 19, *Lactobacillus plantarum*, 2.5 g beta-glucans, 2.5 g inulin, 2.5 g pectin, 2.5 g resistant starch), did not show prevention of relapse 24 months later (Chermesh et al 2007). In another study (duration: 13.0 ± 4.5 months) (Fujimori et al 2007), 10 non-hospitalised patients with active CD were treated with high-dose symbiotic therapy consisting of bifidobacterium and lactobacillus (75 billion colony-forming units (CFU)/day) + psyllium (9.9 g/day); only three patients did not experience any benefit.

These differing results may be due to small sample size in the studies.

Ulcerative colitis (UC)

Information from a number of animal studies has indicated that prebiotics may be of therapeutic value in UC and human studies, which appear to show similar results. A small placebo-controlled study of 19 patients with active UC (mild/moderate) received prebiotic treatment (oligofructose-enriched inulin, ratio 1:1) plus 3 g/day of mesalazine for 2 weeks indicated less abdominal pain and a reduction of intestinal inflammation as determined by calprotectin levels which decreased after a week of treatment but there was no change in prostaglandin E2 (PGE2) secretion and interleukin (IL)-8 production (Casellas et al 2007).

In a double-blind, randomised controlled pilot study of 18 patients with active UC, synbiotic treatment with 12 g oligofructose-enriched inulin (1:1) plus *Bifidobacterium longum* for 4 weeks resulted in reduced colonic inflammation, decreased human beta-defensin mRNA, tumour necrosis factor-alpha (TNF-alpha) and IL-1alpha, and improved sigmoidoscopy scores, although there was no difference in clinical measures (Furrie et al 2005).

In a randomised, controlled study by Fujimori et al (2009), the efficacy of synbiotic therapy compared to either prebiotics or probiotics was conducted in 120 outpatients with UC in remission. Each group of patients enrolled in the study was treated with either ingesting one capsule per day consisting of *B. longum* 2×10^9 colony-forming units (probiotic group), or 2 × 4 g doses of psyllium (prebiotic group) or being treated with both the probiotic + prebiotic (synbiotic group) for 4 weeks. At the end of the study, C-reactive protein decreased significantly (P = 0.04) and the quality

of life scores in the Inflammatory Bowel Disease Questionnaires (IBDQs) were also significantly improved for the symbiotic treated group; the score for bowel function was significant in the prebiotic group ($P = 0.04$).

Pouchitis

There are only a limited number of studies that have investigated the role of prebiotics or synbotics in pouchitis.

A small open-label study of 10 patients with pouchitis (antibiotic-refractory or antibiotic-dependent), treated with a symbiotic mixture of FOS + *Lactobacillus rhamnosus* GG (LGG), reported complete remission as determined by clinical and endoscopic criteria (Friedman & George 2000). In a crossover study of 20 patients with ileal pouch–anal anastomosis, daily treatment with 24 g of inulin or placebo for 3 weeks did not change the clinical activity scores although there was a reduction in inflammation ($P = 0.01$), and increased faecal butyrate concentrations; lactobacilli and bifidobacteria levels were not affected although a significant reduction in faecal levels of *Bacteroides fragilis* was reported (Welters et al 2002).

Constipation

The use of lactulose has a long history and it has been used successfully to treat constipation (de Schryver et al 2005, Petticrew et al 1997). Likewise, FOS and GOS also have laxative effects; Gibson et al (1995) demonstrated that feeding 15 g of FOS or 15 g inulin per day could significantly increase stool output.

Diarrhoea

Various prebiotic components have been utilised in clinical trials to evaluate their efficacy in diarrhoea of different origins.

Traveller's diarrhoea

A double-blind, randomised controlled study of 244 people travelling to medium–high risk destinations and at risk of traveller's diarrhoea reported that those subjects who were treated with FOS (10 g) experienced increased wellbeing and less severe diarrhoea although there was no significant difference in the incidence of diarrhoea (Cummings et al 2001).

Clostridium difficile-associated diarrhoea (CDAD)

In a randomised, controlled, double-blind study, 142 patients with CDAD in hospital were randomised to receive oligofructose or placebo as well as the standard antibiotic treatment for 30 days and followed up 30 days later; the prebiotic-treated patients had increased bifidobacteria levels, reduction in the rate of relapse and experienced significantly less diarrhoea (8% vs 34% in the placebo group, $P < 0.001$) (Lewis et al 2005a).

In another randomised controlled double-blind study of 435 patients in hospital, who were receiving all antibiotics, patients were randomised to receive oligofructose for 7 days or a placebo, with follow-up for another 7 days, there was a significant increase in bifidobacteria concentrations in the prebiotic group although there was no difference in the incidence of *Clostridium difficile* (Lewis et al 2005b).

Allergic disease and food hypersensitivity

A Cochrane systematic review (Osborn & Sinn 2007) investigated the effectiveness of prebiotics for the prevention of allergic disease or food hypersensitivity in infants; of the seven studies that were assessed, there were only two ($n = 432$) that reported an allergic disease outcome; meta-analysis determined no significant difference in eczema. The study authors noted the marked heterogeneity with regard to the study populations, measures of eczema and also the prebiotics used. Moro et al (2006) reported that FOS + GOS combination reduced the development of atopic dermatitis in their study of infants at high risk from atopy. In contrast, Ziegler et al (2007) did not select infants based on their allergy risk and found no significant difference in eczema.

In a prospective, randomised, double-blind, placebo-controlled study of 134 infants, Arslanoglu et al (2008) reported that healthy infants of parents with a history of atopy, fed a hypoallergenic prebiotic-supplemented formula containing a mixture (8 g/L) of neutral short-chain GOS and long-chain FOS ($n = 66$ intervention group; $n = 68$ placebo group), during the first 6 months of life had fewer infections and allergic symptoms at follow-up. In another study by the same team, infants fed milk formula plus 8 g/L GOS/FOS for 6 months resulted in beneficial antibody profile (van Hoffen et al 2009).

Cancer

A randomised, double-blind, placebo-controlled study investigated the effects of a symbiotic mixture on immune modulation in patients with colon cancer ($n = 34$) post 'curative resection' and polypectomised patients ($n = 40$); the symbiotic treated group received encapsulated *Lactobacillus rhamnosus* GG (LGG) 1×10^{10} CFU + *Bifidobacterium lactis* Bb12 (Bb12) 1×10^{10} CFU + 10 g of inulin enriched with oligofructose on a daily basis for 12 weeks; overall both groups receiving the symbiotic treatment demonstrated minor effects on some of the immune markers (Roller et al 2007). Likewise in another randomised, double-blind, placebo-controlled study of 80 patients (37 colon cancer and 43 polypectomised) by this group, a number of colorectal cancer biomarkers were positively affected by 12 weeks' symbiotic treatment (Rafter et al 2007).

Bone health

A double-blind, randomised, crossover study with a 9-day intervention period and 19 days washout period investigating calcium absorption in 12 menopausal women reported an increased calcium absorption ($P = 0.04$) in women taking the yoghurt drink (2 × 200 mL/day) rich in transgalactooligosaccharides (20 g/day) (van den Heuvel et al 2000).

Griffin et al (2002) conducted a large, randomised, crossover study of 59 young girls to investigate the effect of either inulin or inulin + oligofructose (8 g/day) for 3 weeks with a 2-week washout period, in addition, all participants took 1500 mg/day calcium (2 glasses calcium-fortified orange juice); at the end of the study, the inulin + oligofructose-treated group was reported to have significantly higher calcium absorption. Studies by Abrams et al (2005) have supported these findings.

OTHER USES

Liver disease — hepatic encephalopathy

Lactulose has been used routinely as part of the treatment for hepatic encephalopathy although the exact mechanism of its action is still undetermined; lactulose treatment results in normalising of the intestinal microflora, lowering faecal pH and increasing nitrogen excretion (Ballongue et al 1997, Elkington et al 1969).

Pancreatitis

Some studies have found that symbiotic supplementation was more beneficial than prebiotics alone for improved systemic inflammatory response in patients with acute pancreatitis (Olah et al 2005).

DOSAGE RANGE

Prebiotics are known to induce unfavourable side effects such as abdominal pain, bloating, borborygmi and excessive flatulence when used in high doses; these symptoms may diminish over time or with dose reduction. However, the initial doses should be small and increased gradually dependent on gastrointestinal tolerance. GOS: 8–15 g/day; higher doses may lead to undesirable gastrointestinal symptoms such as cramping, abdominal pain and diarrhoea. FOS: 10–15 g/day; some report adverse side effects at 14 g, whereas 10 g is better tolerated.

TOXICITY

Overall, prebiotics have a good profile but their consumption can result in some adverse side effects. (See ADVERSE REACTIONS below.)

ADVERSE REACTIONS

There are many reports of transient gastrointestinal side effects of prebiotic treatment; symptoms such as abdominal pain, bloating, diarrhoea and flatulence are commonly reported. The severity of the symptoms is dose dependent. The more troubling aspect of prebiotics is their potential for enhancing bacterial translocation, although the findings are mixed.

Studies in rats have shown that both inulin and FOS not only increased intestinal lactobacilli and bifidobacteria colonisation, but also enhanced translocation of *Salmonella enterica serovar Enteritidis* and the caecal contents also contained *Salmonella* although calcium administration was noted to resolve this problem (Bovee-Oudenhoven et al 2003, Ten Bruggencate et al 2004). Reduced bacterial translocation to the liver has been reported in rats with Dextran Sulphate Sodium (DSS)-induced colitis when fed oligofructose, whereas feeding multiple components such as oligofructose, inulin, and *Bifidobacterium infantis DSM 15158* resulted in increased bacterial translocation (Osman et al 2006). In another animal study, reduced bacterial translocation to the liver and mesenteric lymph nodes in rats was noted when administered *Lactobacillus plantarum 299v* and treatment with oatmeal as the prebiotic did not prevent this (Mangell et al 2006). In a human study of 72 elective surgery patients, synbiotic feeding did not result in increased bacterial translocation (Anderson et al 2004).

SIGNIFICANT INTERACTIONS

Controlled studies are not available and at present there are no known drug interactions with prebiotics.

CONTRAINDICATIONS AND PRECAUTIONS

Prebiotics/synbiotics are contraindicated in those people who are hypersensitive to any component of the prebiotics/synbiotics-containing product. People with IBS who may have increased gas production should avoid high intakes of prebiotics (Serra et al 2001). People with lactose intolerance should use lactulose with caution.

PREGNANCY USE

Prebiotics found in the food chain are safe to consume in pregnancy.

PRACTICE POINTS/PATIENT COUNSELLING

- Prebiotics can be obtained from usual foods such as artichoke, asparagus, bananas, chicory, garlic, leek, onions, wheat.
- Prebiotics may be combined with probiotics to produce synbiotics that will enable the two components to work together in synergy.
- Although prebiotics may improve the long-term bowel flora, prebiotic supplementation has many other benefits not associated with direct colonisation of the gastrointestinal tract.
- There is some evidence that prebiotics support both the development and the maintenance of a healthy immune system.
- Prebiotics have been used in the management of diarrhoea, constipation, other gastrointestinal disorders, bone health, allergic disease and food sensitivity.
- Continuous intake of prebiotics is required in order to maintain their health benefits.
- Some individuals may experience greater gastrointestinal discomfort with use, although some symptoms may subside over time and dose reduction can improve tolerance

PATIENTS' FAQs

What will this supplement do for me?

Studies have shown that prebiotics are beneficial in the treatment of digestive disorders such as diarrhoea, constipation and some inflammatory bowel diseases and also other conditions, such as IBS, food

allergies and eczema. There is some evidence that prebiotics may be useful for bone health.

When will it start to work?

Usually prebiotics can exert beneficial effects for digestive disorders such as constipation and diarrhoea within 1–2 weeks, although continuous use for several weeks/months may produce long-term benefits and be necessary in the treatment of other disorders.

Are there any safety issues?

Generally, prebiotics have a good safety profile; however, high-dose supplements should be used under supervision in immunocompromised patients.

Probiotics

HISTORICAL NOTE There is a long history of consuming fermented foods and beverages containing microorganisms to improve health. The term 'probiotic' is derived from Greek and means 'for life.' As far back as 1908, Metchnikoff, the Nobel laureate, stated that 'ingested lactobacilli can displace toxin-producing bacteria, promoting health and prolonging life' (Elmer 2001). The term 'probiotics' was first coined in 1965 and has since been applied to those live microorganisms that are able to promote health when consumed in sufficient quantities (FAO/WHO 2001). This is in contrast to the term 'prebiotics' which are dietary components. Although it has taken the most part of a century for scientists to investigate their health benefits, there are now several thousand studies published on probiotics, the majority published since 2000.

BACKGROUND AND RELEVANT PHARMACOKINETICS

At birth, the gastrointestinal tract is sterile but soon becomes colonised with microorganisms. The growth of normal gut flora is influenced by factors such as composition of the maternal gut microflora, diet, degree of hygiene, use of antibiotics or other medication, the environment and possibly genetic aspects. These microorganisms also confer health benefits by preventing the colonisation of the

Clinical note — Prebiotics and synbiotics
Prebiotics are components that modify the environment of the gastrointestinal tract to selectively favour proliferation of the beneficial intestinal microflora, lactobacilli and bifidobacteria (Gibson & Roberfroid 1995). Herbal and nutritional prebiotics include the fibre supplement known as slippery elm (*Ulmus fulva*), oligofructose and inulin. Synbiotics contain both pre- and probiotics.

gastrointestinal tract with pathogenic microorganisms. The gut bacteria also carry out a number of biochemical functions, including deconjugation and dehydroylation of bile acids, the conversion of bilirubin to urobilinogen, generation of short-chain fatty acids, the metabolism of cholesterol to coprostanol and production of vitamins K, B1, B2, B6 and B12 (Bengmark 1998, Hill 1997).

The gastrointestinal microflora is mostly resilient to change and remains fairly constant, although research over the years has shown that components such as pre- and probiotics can modulate the gut microflora. It has been estimated that the intestines are host to 10^{14} microbes representing 400–500 different species (Ouwehand et al 2002) and also includes yeasts, mostly *Candida albicans* (<0.1% of the microbiota) (Vandenplas et al 2007). This microflora has many important roles including enhancement of the gastrointestinal barrier function, nutrient metabolism, modulating immune function and producing potential health-promoting components (Bengmark 1998, Fotiadis et al 2008).

Probiotics can be obtained from the consumption of fermented foods as well as supplements. In order for a probiotic microorganism to show therapeutic effects, it must survive gastric acid and juices and bile salts, and should be viable in the digestive system. However, the majority of microorganisms ingested do not survive these conditions, and regular intake is required for successful colonisation (Goldin & Gorbach 1984).

Recently, the concept that probiotics should be viable/live has been evaluated. Studies have shown that bacterial DNA sequences may have similar effects as the live bacteria, and therefore, colonisation of the intestinal tract may not be a prerequisite for the action of probiotics (Jijon et al 2004, Rachmilewitz et al 2002). In addition, the mucosal immune system may not require direct contact with probiotics for beneficial effects as other routes of administration (such as the parenteral route) are also effective (Rachmilewitz et al 2004, Sheil et al 2004). However, there are also significant species and strain differences between the probiotic microorganisms, and therefore, they do not all share the same characteristics.

At present, there are numerous proposed uses of probiotics, and reports of their beneficial effects cover a wide range of diseases and conditions.

CHEMICAL COMPONENTS

Probiotics include bifidobacteria (e.g. *B. bifidum*); lactobacilli such as *L. acidophilus*, *L. bulgaricus*, *L. casei*, *L. gassen*, *L. plantarum*, *L. reuteri* and *L. GG* (variant of *L. casei* subsp. *rhamnosus*, named after Drs Gorbach and Goldin who first isolated the strain in 1980) and *Lactobacillus* strain LB; and Streptococci such as *Saccharomyces boulardii* (a yeast), *Streptococcus thermophilus* and *Streptococcus salivarius* (Hedin et al 2007).

FOOD SOURCES

Fermented foods, such as sauerkraut (Dedicatoria et al 1981) and kefir (Garrote et al 2001), are sources of probiotics. More commonly, dairy sources such as yoghurt may also contain probiotics, especially *L. acidophilus* and bifidobacteria strains.

DEFICIENCY SIGNS AND SYMPTOMS

Clear deficiency signs are difficult to establish because the symptoms may vary enormously. Local signs and symptoms of disruption of the intestinal microflora leading to an imbalance (intestinal dysbiosis) include bloating, flatulence, abdominal pain, diarrhoea and/or constipation and fungal overgrowth (such as *Candida*). An imbalance of gastrointestinal microflora can be caused by the use of antibiotics, and chronic diarrhoea or constipation. Administration of probiotics is used as a means of restoring this microflora imbalance (Bengmark 1998, Hedin et al 2007, Hoveyda et al 2009, Kajander et al 2008, McFarland 2006, 2007, McFarland & Dublin 2008).

MAIN ACTIONS

Numerous mechanisms have been proposed by which probiotics could exert their health-promoting effects.

Immune modulation

Immune system modulation and the prevention of gastrointestinal tract colonisation by a variety of pathogens are among the most important actions of probiotics.

Probiotics compete for receptor sites that prevent adhesion of pathogenic bacteria to the gut wall and produce inhibitory substances such as bacteriocins, lactic acid and toxic oxygen metabolites. Of the toxic oxygen metabolites, hydrogen peroxide is of major importance as it exerts a bactericidal effect on many pathogens (Kaur et al 2002). The ability to produce bacteriocins, hydrogen peroxide and other antimicrobial compounds is strain dependent and requires the presence of folic acid and riboflavin in the case of lactobacilli. Binding to the gut wall also initiates signalling events that result in the synthesis of cytokines (Vanderhoof & Young 2003). Studies in germ-free mice have proven that intestinal bacteria are essential for a healthy systemic immune system (Falk et al 1998).

Probiotics may also produce anti-inflammatory components, decrease the luminal pH, compete for nutrients with potential pathogens and as a result of inhibitory substances produced by probiotics. These antimicrobial substances produced by probiotics include bacteriocins, lactic acid and hydrogen peroxide (Kaur et al 2002).

A growing body of evidence indicates that in particular lactobacilli and bifidobacteria can

modulate the immune system at both the systemic and the mucosal level affecting many cell types (e.g., epithelial cells, dendritic cells, natural killer cells, etc). Consequently, health benefits induced by probiotics include the stabilisation of the microflora, enhancing the mucosal defence effects via tight junction integrity between enterocytes and downregulating proinflammatory cytokines (e.g. tumour necrosis factor alpha), and inducing regulatory cytokines (plus interleukin (IL)-10 and transforming growth factor-beta) as reported in patients with inflammatory bowel disease (IBD) (Borruel et al 2002, Pathmakanthan et al 2004). However, these probiotic-induced immunomodulatory characteristics are species and strain specific.

Gastrointestinal effects

Probiotic therapy has been shown to be beneficial in promoting healthy digestive function, eradicating various gastrointestinal infections and managing gastrointestinal diseases.

Helicobacter pylori infection

Several in-vitro studies have shown that certain probiotics inhibit or kill *H. pylori*, prevent its adhesion to mammalian epithelial cells and prevent IL-8 release. In-vivo models demonstrate that pretreatment with a probiotic can prevent *H. pylori* infections and/or that administration of probiotics markedly reduces an existing infection. Clinical efficacy has also been evaluated for the use of probiotics as prevention or treatment and has shown promising results according to a review of six clinical studies (Hamilton-Miller 2003).

Probiotics such as *Lactobacillus* spp exhibit antimicrobial effects against *H. pylori* infection of the gastric mucosa by releasing bacteriocins and limiting adhesion to epithelial cells (Gotteland et al 2006).

Inflammatory bowel disease

This is characterised by alterations in gastrointestinal microflora with reports of increased bacteroides, *Escherichia coli* and enterococci and reduced lactobacilli bifidobacteria (Neut et al 2002, Swidsinski et al 2002). As treatment with probiotics is associated with restoring colonic microbiota and decreasing inflammation, this has been investigated in a number of gastrointestinal disorders, including IBD and antibiotic associated diarrhoea.

Chemopreventative effects

Select probiotics may have anticancer properties. Different strains of *Lactobacillus acidophilus* and bifidobacteria have been studied to investigate their antimutagenic activity against chemical mutagens (Lankaputhra & Shah 1998).

Antimutagenic activity against chemical mutagens and promutagens has been demonstrated for different strains of *Lactobacillus acidophilus*, bifidobacteria and the organic acids usually produced by these probiotics, with live cells producing the most positive results (Lankaputhra & Shah 1998). Some probiotics also reduce faecal enzymes implicated in cancer initiation, by producing butyric acid, which affects the turnover of enterocytes and neutralises the activity of dietary carcinogens, such as nitrosamines. Additionally, enhancing host immunity and qualitative and quantitative changes to the intestinal microflora and physicochemical conditions are important contributing factors (Hirayama & Rafter 1999).

OTHER ACTIONS

Several clinical studies have investigated lipid-lowering activity of probiotics (See *Clinical use* below).

CLINICAL USE

It is generally agreed that a probiotic must be capable of colonising the intestinal tract to influence human health. Currently, one of the most extensively studied probiotics is *Lactobacillus GG*. Probiotic supplements are usually standardised in terms of the amount of living organisms per unit of volume, and dosages range from 1 billion colonies to as high as 450 billion daily.

Gastrointestinal infections

Probiotics may have a role in the management of various infections and particularly gastrointestinal infections, such as bacterial induced diarrhoea, *Helicobacter pylori*, recurrent *Clostridium difficile*-associated disease and pancreatitis.

Diarrhoea

Various probiotic strains have been subjected to clinical trials to evaluate their efficacy in diarrhoea of different origins.

Infectious diarrhoea

A Cochrane review analysed results from 23 randomised controlled trials (RCTs) ($n = 1917$) evaluating the role of probiotic agents in acute diarrhoea proven or presumed to be caused by an infectious agent (Allen et al 2004). The majority of subjects were infants or children ($n = 1449$; age < 18 years). The review concluded that probiotics reduced the risk of diarrhoea at 3 days, and the mean duration of diarrhoea by 30.5 h and supplementation was a useful adjunct to rehydration therapy in treating acute, infectious diarrhoea in adults and children. Several different probiotics were tested: all were lactic acid bacilli, except in two studies that tested the yeast *Saccharomyces boulardii*. With the exception of a trial of live *Streptococcus thermophilus* and *Lactobacillus bulgaricus*, a beneficial effect in the probiotic group compared to controls was observed in all trials.

Many double-blind, prospective, randomised trials that utilised *S. boulardii* in children with acute gastroenteritis have demonstrated a significant improvement (Vandenplas et al 2007).

A more recent meta-analysis of eight RCTs ($n = 988$) by Szajewska et al (2007) concluded that although there was no reduction in the number of stools for any given time period, the duration of diarrhoea was much shorter as a result of *Lactobacillus GG* treatment; however, the authors noted that the heterogenicity and methodological considerations of the studies limited the strength of the conclusion.

In order to determine the dose-dependent effect of *Lactobacillus GG* on faecal rotavirus shedding, Fang et al (2009) conducted an open-label randomised study where 23 children with rotavirus gastroenteritis were treated for 3 days with a daily dose of LGG 0 colony-forming units (CFU)/day (control group, $n = 6$) or administered 2×10^8 CFU/day (low-dose group, $n = 9$) or 6×10^8 CFU/day (high-dose group, $n = 8$). The results of this study demonstrated that the high-dose probiotic group was the only group who experienced a significant reduction of rotavirus levels in stool samples (86% after 3 days).

Due to the differing findings from studies in this area, further investigation is required in order to confirm/clarify the most appropriate probiotic strains to be used, optimal dosage and length of time for treatment. Most findings agree that treatment with certain probiotic strains (e.g. *S. boulardii*, *L. casei GG*, *L. acidophilus*, *L. bulgaricus* and *L. reuteri*) result in a 24-h (17–30 h) reduction in diarrhoea duration, and the beneficial effects are more pronounced if administered early in the illness (Vandenplas et al 2007).

Travellers' diarrhoea

Travellers' diarrhoea is the most common health problem in those visiting developing countries, affecting 20% to more than 50% of tourists. Although it is usually benign, travellers' diarrhoea represents a considerable socioeconomic burden for both the traveller and the host country. The most common enteropathogen is *Escherichia coli*, although a number of other microorganisms are also implicated.

Some clinical studies have found various probiotics somewhat effective against travellers' diarrhoea; however, no probiotic has been able to demonstrate clinically relevant protection worldwide (Rendi-Wagner & Kollaritsch 2002).

A large, randomised, placebo-controlled, double-blind study of the efficacy of *Lactobacillus GG* in preventing travellers' diarrhoea involved 820 people on holiday to Turkey to two destinations. The group was randomly assigned either *L. GG* or placebo in identical sachets. On the return flight, each participant completed a questionnaire indicating the incidence of diarrhoea and related symptoms during the trip. Of the original group, 756 (92%) subjects completed the study. The overall incidence of diarrhoea was 43.8% (331 cases), and the total incidence of diarrhoea in the *L. GG* group was 41.0% compared with 46.5% in the placebo group, indicating an overall protection of 11.8%. Protection rates varied between two different destinations, with the maximum protection rate reported as 39.5% and no side effects reported (Oksanen et al 1990).

In another placebo-controlled double-blind study, two doses (250 and 1000 mg) of *Saccharomyces boulardii* were administered prophylactically to 3000 Austrian travellers. A significant reduction in the incidence of diarrhoea was observed, with success depending directly on the rigorous use of the preparation. A tendency was noted for *S. boulardii* to have a regional effect, which was particularly marked in North Africa and in Turkey. The effect was dose dependent, with participants taking the higher dose of probiotics experiencing the lowest incidence of travellers' diarrhoea (29%) and little difference observed between low-dose *S. boulardii* supplementation (34%) and placebo (39%). Treatment was considered very safe (Kollaritsch et al 1993).

Positive results were confirmed more recently in a meta-analysis of 12 randomised, controlled clinical trials that investigated the role of probiotics in the prevention of travellers' diarrhoea (McFarland 2007). The authors concluded that probiotics significantly prevent travellers' diarrhoea (RR = 0.85, $P < 0.001$), and *Saccharomyces boulardii* and a mixture of *Lactobacillus acidophilus* and *Bifidobacterium bifidum* demonstrate the major beneficial effects.

Antibiotic-induced diarrhoea

A recent Cochrane review by Johnston et al (2007) assessed the efficacy of probiotics for the prevention of antibiotic associated diarrhoea in children (0–18 years). Although per protocol analysis was positive for the use of probiotics in reducing diarrhoea, these findings were not significant in the intention to treat analysis and the routine use of probiotics could not be recommended. Recommendations were made for future research using probiotics most likely to be useful agents such as *Lactobacillus GG*, *Lactobacillus sporogenes* and *Saccharomyces boulardii* at 5–40 billion CFU/day.

Previously, a meta-analysis (D'Souza et al 2002) which assessed nine randomised, double-blind, placebo-controlled trials came to a positive conclusion. Four of the studies tested the yeast *S. boulardii*, four used lactobacilli, one used a strain of enterococcus-producing lactic acid and in three studies a combination of probiotics was administered. Overall, *Lactobacillus* spp. and *Saccharomyces boulardii* were reported to be effective in preventing antibiotic associated diarrhoea.

Clostridium-difficile-associated diarrhoea (CDAD)

Clostridium difficile is a common cause of diarrhoea associated with treatment with antimicrobial and/or antibiotic medication and can potentially progress to colitis, pseudomembranous colitis, toxic megacolon and death. In spite of antimicrobial therapy, recurrence is common, and increasingly, probiotic supplementation has been investigated as a potential treatment for CDAD.

A meta-analysis by McFarland (2006) assessed six blinded randomised controlled trials ($n = 354$ patients) that used a mixture of probiotics in the management of *Clostridium difficile*-associated diarrhoea (CDAD). The results showed that only *S. boulardii* supplementation resulted in a significant reduction in recurrence. These findings are in contrast to an earlier meta-analysis by Dendukuri et al (2005), where a role for probiotic use in CDAD was not supported in all the studies; the authors reported methodological flaws in some of the studies although some benefit of probiotic therapy was seen in patient subgroups, particularly those characterised by severe CDAD and high use of vancomycin.

AIDS-related diarrhoea

In a small study, 24 women with AIDS/HIV, aged 18–44 years, who were not being treated with antiretrovirals and had moderate diarrhoea, were given either a yoghurt fermented with *Lactobacillus delbruekii* var *bulgaricus* and *Streptococcus thermophilus*, supplemented with probiotic *Lactobacillus rhamnosus* GR-1 and *L. reuteri* RC-14 or an unsupplemented yoghurt for 15 days. Women receiving the supplemented probiotic–yoghurt experienced less diarrhoea, flatulence and nausea than those receiving the unsupplemented yoghurt (Anukam et al 2008).

S. boulardii has also been used for HIV diarrhoea (Saint-Marc et al 1991). Trois et al (2008) investigated the effect of probiotics on the immune response in a randomised, double-blind, controlled trial of two groups of children (2–12 years) infected with HIV. The study of 77 children administered either a formula containing *Bifidobacterium bifidum* + *Streptococcus thermophilus* −2.5 × 10^{10} CFU or a standard formula on a daily basis for 2 months. At the end of the study, there was an increase in CD4 cell count suggestive of improved immune response.

Irritable bowel syndrome

People suffering from irritable bowel syndrome (IBS) sometimes experience symptoms of abdominal cramping and either diarrhoea or constipation or a combination of both. They can also experience symptoms of abdominal distension, cramping and pain. Although the aetiology of IBS is still unknown, there is growing suspicion that there is a persistent, mild inflammatory state with changes in mucosal function or structure and an associated imbalance of intestinal flora (Camilleri 2006). This imbalance can lead to inefficient metabolism of nutrients and the formation of gas and short-chain fatty acids, both of which induce propulsive contractions and accelerate colonic transit or enhance fluid and sodium absorption in the colon. As such, clinical trials have been conducted to clarify the role of probiotics in this condition, so far producing promising results.

A 2008 meta-analysis concluded that probiotics can result in improved symptom relief in the treatment of IBS (McFarland & Dublin 2008). Twenty randomised controlled clinical trials ($n = 1404$) were reviewed, and either single or multiple probiotics were used for varying time periods ranging from 2 to 24 weeks (median = 4 weeks); overall, there were insufficient data to draw conclusions about the most effective probiotic strains or the assessment of individual IBS symptoms.

Similarly, a 2009 systematic review and meta-analysis by Hoveyda et al (2009) reported that probiotic therapy for several weeks may result in modest improvement in overall symptoms of IBS. A total of 14 randomised placebo-controlled trials of varying length (from 4 weeks to 6 months although the majority lasted 8 weeks or less) of the intervention period were included in the analyses; the probiotic therapy varied in the type of probiotics used as well as the dose and strength; in addition, some studies used a single agent and others used combinations of multiple microorganisms.

Most recently, Kajander et al (2008) conducted a randomised, placebo-controlled study for 5 months and investigated the effects of a daily dose of a multispecies probiotic supplement (*Lactobacillus rhamnosus GG*, *L. rhamnosus* Lc705, *Propionibacterium freudenreichii* ssp. *shermanii* JS and *Bifidobacterium animalis* ssp. *lactis* Bb12) in 86 patients with IBS. Active treatment resulted in relief from IBS symptoms (especially distension and abdominal pain) and stabilisation of the intestinal microflora compared with placebo.

Similarly, earlier studies had reported favourable results with supplementation of *L. plantarum* for 4 weeks in successfully treating symptoms of IBS and improving bowel function (Nobaek et al 2000, Niedzielin et al 2001).

Not all clinical studies have produced positive results. A large randomised, parallel group, double-blind study by Drouault-Holowacz et al (2008) investigated the effects of four strains of lactic acid bacteria on symptoms of IBS in 100 patients over a 4-week period. Overall, there was little difference between the two groups, although some improvement was noted regarding abdominal pain and stool frequency in some patient subgroups.

Some of the reported differences of the effects of probiotics regarding IBS-related symptoms may be due to strain differences; it has been suggested that encapsulated *Bifidobacterium infantis* 35624 (dose: 10^8) may be more suitable than *Lactobacillus* (O'Mahony et al 2005, Whorwell et al 2006). Rousseaux et al (2007) demonstrated that oral administration of *L. acidophilus* induced expression of mu-opioid and cannabinoid receptors in human intestinal epithelial cells.

Helicobacter pylori infection

Helicobacter pylori was first discovered in the early 1980s. At that time, triple therapy was advocated and used effectively as a treatment. This consisted of antibiotics, clarithromycin, amoxicillin or metronidazole and proton pump inhibitor, but in recent years, the standard triple therapies have not been so successful. Additionally, triple therapy has been associated with unfavourable side effects such as antibiotic associated diarrhoea. Consequently, there have been attempts to investigate alternative therapies. Generally, studies have found probiotics reduce gastrointestinal symptoms and the side effects of triple therapy; however, findings have been mixed regarding the effect of probiotics on *Helicobacter pylori* eradication (Egan et al 2007). It has been proposed that the different results obtained in studies may be because only some, but not all, strains of probiotics are effective against *H. pylori* (Gotteland et al 2006).

Park et al (2007) studied the effect of *Bacillus subtilis* and *Streptococcus faecium* as probiotic supplements on *H. pylori* eradication in a randomised study. The study of 352 *H. pylori*-positive patients compared standard triple therapy plus probiotics to triple therapy as stand-alone treatment. After an 8-week intervention period, both patient groups were followed up for a further 4 weeks. The group receiving combination therapy with adjunctive probiotics

experienced less diarrhoea than standard treatment and also showed a higher eradication rate (83.5 vs 73.3%, $P = 0.027$) in comparison to the usual care group. The same year, a double-blind randomised placebo-controlled crossover study by Imase et al (2007) utilised *Lactobacillus reuteri* strain SD2112 tablets in the management of 33 patients infected with *H. pylori* and asymptomatic volunteers. Once again, probiotic treatment was effective in suppressing *H. pylori* infection.

The same researchers also investigated a *Clostridium butyricum* preparation (CBM588) as a potential eradication therapy for *H. pylori* in a study of 19 patients who were randomised to receive regular doses of CBM588, or double doses of CBM588, and a group that was not treated with this probiotic. The results were favourable for the use of the probiotic; diarrhoea was absent in the group that was treated with double doses of CBM588, and in addition, *C. difficile* toxin A could not be detected (Imase et al 2008).

In contrast, a recent pilot study of 65 dyspeptic patients with confirmed *H. pylori* infection investigated the potential beneficial effects of *Lactobacillus reuteri* (*L. reuteri*) or a high concentration of probiotics in addition to the standard triple therapies for eradication of the infection and found all treatments to be ineffective. The participants received a standard 7-day triple therapy, or standard treatment plus *L. reuteri* supplementation, or they received the same 7-day triple therapy plus a probiotic mixture or a 14-day standard triple therapy plus a probiotic mixture. The authors reported that 4–6 weeks after treatment, the 7–14-day triple therapy with or without probiotic supplementation failed to achieve acceptable *H. pylori* eradication rates (Scaccianoce et al 2008).

In a small, double-blind, placebo-controlled study of 40 patients with *H. pylori* infection, *Lactobacillus reuteri* ATCC 55730 supplements or placebo was administered once a day for 4 weeks; the probiotic-treated group reported significantly less gastrointestinal symptoms ($P < 0.05$) compared to their pretreatment status. However, the probiotic treatment did not affect the eradication rates (Francavilla et al 2008).

Gotteland et al (2008) investigated the potential for an additive or synergistic inhibitory effect of cranberry juice and *Lactobacillus johnsonii* La1 (La1) in the management of *H. pylori* infection in children. The multicentric, randomised, controlled, double-blind study of 295 children aged 6–16 years compared four different treatments: cranberry juice plus viable La1, cranberry juice plus nonviable La1, placebo juice plus viable La1 or placebo juice plus nonviable La1 (untreated controls). All groups consumed their juice plus probiotic on a daily basis for 3 weeks. Treatment with either cranberry juice or La1 was successful and produced significant differences ($P < 0.01$) in eradication rates compared to the control group; however, no synergistic effect was noted when cranberry juice and probiotics were combined.

Surprisingly, a large randomised study of 347 patients with *H. pylori* infection found that when standard care was combined with a yoghurt supplemented with *Lactobacillus acidophilus* HY2177, *Lactobacillus casei* HY2743, *Bifidobacterium longum* HY8001 and *Streptococcus thermophilus* B-1, a greater incidence of side effects was reported. Adverse effects included diarrhoea and having a metallic taste in the mouth (69/168) compared to the standard care group 26.3% (47/179) ($P = 0.003$) (Kim et al 2008). Adjunctive probiotic treatment did not improve eradication rates beyond standard care in the study.

In contrast, in a recent prospective open study (Hurduc et al 2009), 90 symptomatic children (aged 3–18 years) with *H. pylori* infection were randomised into two groups: one group ($n = 48$) was treated with *Saccharomyces boulardii* (250 mg b.i.d., for 4 weeks) and the other group ($n = 42$) served as the control group; all the children were treated with the standard triple eradication therapy (omeprazole/esomeprazole, amoxicillin and clarithromycin) for 7–10 days. After 4–6 weeks, there was little difference in the eradication rate (control = 80.9%, *S. boulardii* group = 93.3%; no significant difference). However, *S. boulardii* plus the standard eradication treatment resulted in a significant reduction in the incidence of side effects (30.9 vs 8.3% in the probiotic group; $P = 0.047$).

Inflammatory bowel disease

Probiotics are also being used as adjunctive therapy for Crohn's disease (CD) and IBD (Goh & O'Morain 2003, Guslandi 2003a, 2003b, Kanauchi et al 2003, Karthik 2003, Marteau et al 2003, Rutgeerts 2003). Due to differences in study design, number of participants and dose and strain of probiotic used, it is difficult to assess the role of probiotics in IBD. Overall, present research indicates a limited role for probiotics in CD, the results for ulcerative colitis (UC) are more promising, and there does seem to be a beneficial effect in pouchitis.

Crohn's disease

Only a limited number of studies have indicated a role for probiotics in the remission of CD. In one study, Guslandi et al (2000) compared *S. boulardii* plus mesalazine with mesalazine alone and found that adjunctive probiotic treatment resulted in fewer relapses.

Supplementation with VSL#3 has also been evaluated. VSL#3 contains a high concentration of eight strains of lactic acid bacteria, including *B. breve*, *Bifidobacterium longum*, *B. infantis*, *L. acidophilus*, *L. plantarum*, *L. casei*, *Lactobacillus bulgaricus* and *Streptococcus thermophilus*. A study of 40 patients randomised to 3 months of rifaximin followed by 9 months of VSL#3 or to 12 months of mesalazine also reported relapse prevention with probiotic therapy (Campieri et al 2000).

The majority of other studies, including randomised double-blind placebo-controlled trials, have not confirmed the utility of LGG or *Lactobacillus johnsonii* La1 in the remission of CD (Hedin et al 2007). Similarly, studies that have administered probiotics for the treatment of active CD have also provided mixed results and mainly because of

concurrent use of medications during the intervention period (e.g., prednisolone use or metronidazole) (Gupta et al 2000).

A Cochrane systematic review by Rolfe et al (2006) did not advocate a role for probiotics in CD based on the available evidence, suggesting that because all studies enrolled small numbers of patients, they may have lacked statistical power to show differences should they exist. Seven RCTs were identified that had utilised a variety of probiotics such as *Lactobacillus GG*, *E. coli* Nissle and *Saccharomyces boulardii*; most of the studies had a relatively small number of participants with different treatment protocols, probiotics and outcome measures, making it difficult for comparisons to be made.

Ulcerative colitis

A number of studies have assessed probiotic supplementation for the remission of UC, with probiotics such as lactobacilli or bifidobacteria being found to be ineffective, while *Escherichia coli* Nissle 1917 was reported to be as beneficial as and similar in terms of effectiveness to 5-aminosalicylic acid (Hedin et al 2007).

The role of probiotic therapy during active UC has been confirmed in some studies; clinical benefit of VSL#3 was noted in a few studies. Some investigators have used *E. coli* Nissle 1917 enemas in left-sided UC for direct delivery of the probiotic and others have used probiotic mixtures (*B. breve* strain Yakult, *B. bifidum* strain Yakult and a *L. acidophilus* strain) in fermented milk (Hedin et al 2007).

Pouchitis

Probiotics have also been used in patients with relapsing or chronic pouchitis (Kailasapathy & Chin 2000). While studies have produced inconsistent results, overall there appears to be some evidence to support the therapeutic use of probiotics in postoperative pouchitis (Penner et al 2005) and the general view is that VSL#3 treatment can be effective in controlling this condition.

Studies by Gionchetti et al (2000, 2003) assessed the use of VSL#3 in both primary prevention of pouchitis and maintenance therapy for chronic relapsing pouchitis, demonstrating some success. In their randomised, controlled, double-blind study, 40 patients with relapsing pouchitis in remission received a 6-g daily dose of VSL#3 or a placebo for 9 months. Probiotic treatment resulted in a significantly reduced incidence of pouchitis (Gionchetti et al 2000), but when VSL#3 treatment was ceased, all patients relapsed 3 months later. In a subsequent randomised controlled study to investigate VSL#3 treatment for primary prophylaxis of pouchitis in 40 patients, Gionchetti et al (2003) reported that treatment with VSL#3 resulted in fewer relapses.

In another randomised, double-blind, controlled trial, Mimura et al (2004) also utilised VSL#3 in 36 patients with more severe recurrent pouchitis over a 1-year follow-up period and reported good results regarding maintenance of remission and improved quality of life in the patients.

A combination of probiotics also has been reported to result in beneficial effects; lactobacilli and bifidobacteria in fermented milk were administered to patients who had pouchitis after UC surgery, resulting in some resolution of disease activity (Laake et al 2005).

In contrast, in an uncontrolled study of 31 patients who were treated with antibiotics and were in remission, Shen et al (2005) found little benefit with VSL#3 administered for 8 months.

Probiotics and diverticular disease

It has been suggested that altered bacterial flora is one of the causes of diverticular inflammation (White 2006). Consequently, some investigators have evaluated the role of probiotics in diverticular disease. In an open-label study, 15 patients with diverticular disease were treated with an antimicrobial and charcoal for the first symptomatic episode after enrolment and the second episode was treated with the same therapy followed by *Escherichia coli* Nissle 1917 for 6 weeks. This second treatment resulted in a longer symptom-free duration of a mean of 14 months compared to a mean of 2.4 months in the control group (Fric & Zavoral 2003).

Various studies have attempted to restore the altered microflora using probiotics, but most of these studies have been limited in their design and methods (Sheth & Floch 2009). However, results from these studies appear to be mostly positive, and randomised placebo-controlled studies are needed in order to make recommendations.

Pancreatitis

Probiotic therapy has been investigated in pancreatitis because of the increased risk of bacterial infections. Some animal studies have shown that the use of *L. plantarum* 299v (Mangiante et al 2001) and *S. boulardii* (Akyol et al 2003) reduced bacterial translocation. Human studies have investigated the use of single probiotic agents such as live *L. plantarum* 299v given to 22 patients compared with an inactivated form given to 23 patients; the probiotic-supplemented group had reduced rates of infection and abscess formation (Olah et al 2002). However, these findings are in contrast to those of Besselink et al (2008) (see *Adverse reactions*).

Alcohol-induced liver disease

In a prospective, randomised, clinical study, 66 men with advanced alcohol-induced liver disease received either *Bifidobacterium bifidum* and *Lactobacillus plantarum* 8PA3 or standard therapy (no probiotics) for 5 days. At the end of the study, patients who had received the probiotic therapy had significantly increased numbers of both bifidobacteria (7.9 vs 6.81 log CFU/g) and lactobacilli (4.2 vs 3.2 log CFU/g) compared to the standard therapy group; likewise, the former group had a significant improvement in hepatic enzyme levels (Kirpich et al 2008).

Hepatic encephalopathy

To date, there are only a few reports about the role of probiotics in hepatic encephalopathy; in addition to the conventional management with antibiotics

and lactulose, probiotics may confer favourable changes in intestinal microflora in patients with hepatic encephalopathy.

A recent randomised, controlled, single tertiary centre study with open allocation by Bajaj et al (2008) investigated the effects of probiotic administration on minimal hepatic encephalopathy (MHE), a preclinical stage prior to full-blown hepatic encephalopathy. The probiotics *S. thermophilus*, *L. bulgaricus*, *L. acidophilus*, bifidobacteria and *L. casei* were administered in a yoghurt to a group of patients for 60 days; the study demonstrated a significant rate of MHE reversal.

Colon cancer

A number of factors may be involved in colon cancer risk, and it has been suggested that the colonic microflora may be involved in the aetiology of colorectal cancer. A lower incidence of colon cancer has been associated with the consumption of lactobacillus or bifidobacteria, but the exact mechanism has not been elucidated (Fotiadis et al 2008).

Atopic dermatitis and eczema

It has been widely reported that during the first few months of life, exposure to high-level antigens may predispose some individuals to allergic sensitisation and therefore various atopic conditions. Intestinal microflora plays a major protective role against the development of allergy because it reduces antigen transport through the intestinal mucosa. Consequently, probiotics may have a protective role in the prevention and/or management of atopic dermatitis (AD) and eczema because of their proposed actions (Rosenfeldt et al 2004).

Many clinical studies have investigated probiotic therapy to prevent allergic disease, and some have reported a reduction in the severity of the condition (Furrie 2005, Weston et al 2005).

Prevention of allergy

An early randomised, double-blind, placebo-controlled study showed that perinatal administration of probiotics (*L. rhamnosus GG*) reduced the development of atopic eczema in children by 50% during the first 2 years of life. Some 159 mothers were randomly allocated to receive 2 capsules of placebo or 10^{10} viable *L. rhamnosus GG* daily for 4 weeks before expected delivery. After delivery, capsules were taken for 6 months. During lactation, either the mother or the infant consumed the preparations. In a 4-year follow-up study, it was revealed that the preventive effect of the probiotic on atopic eczema extended beyond infancy (Kalliomaki et al 2003).

The role of probiotics in the prevention and treatment of paediatric AD was reported recently in a meta-analysis by Lee et al (2008); 21 trials were assessed (n = 1898; age: 0–13 years) and analysis of the findings supported a role in prevention of paediatric AD rather than treatment.

Treatment of established allergy

A randomised, double-blind study of 56 young children (aged 6–18 months) with moderate or severe atopic AD found that treatment with *L. fermentum* VRI-033 PCC (1×10^9; Probiomics) twice daily produced a significant reduction in the Severity Scoring of Atopic Dermatitis (SCORAD) index (Weston et al 2005). At week 16, 92% of children receiving probiotics had a SCORAD index that was significantly better than baseline compared with the placebo group (n = 17, 63%) (P = 0.01). Another randomised double-blind study has found that supplementation of infant formulas with viable but not heat-inactivated *L. GG* may have benefits for the management of atopic eczema and cow's milk allergy (Kirjavainen et al 2003).

According to two other placebo-controlled studies, it appears that people with greater allergic responses may be better suited to treatment and experience superior effects. Rosenfeldt et al found that treatment with two *Lactobacillus* strains (lyophilised *L. rhamnosus* 19070-2 and *L. reuteri* DSM 122460) given in combination for 6 weeks to children aged 1–13 years with AD resulted in 56% experiencing improvement (Rosenfeldt et al 2003). Interestingly, the total SCORAD score did not change significantly. Allergic patients with a positive skin prick test response and increased IgE levels experienced a more pronounced response to treatment.

Similarly, a study by Sistek et al (2006) found that a combination of two probiotics (*Lactobacillus rhamnosus* and *Bifidobacterium lactis*) given to children with established AD effectively reduced the SCORAD index among the food-sensitised children, but not in other children. Children in this study received 2×10^{10} CFU/g of probiotic or placebo daily as a powder mixed with food or water.

In contrast, a randomised, double-blind, placebo-controlled trial by Taylor et al (2007) utilising *L. acidophilus* for the first 6 months of life did not find a reduction in the risk of AD in high-risk infants, and in fact the treatment was associated with significantly increased allergen sensitisation. The study was completed by a total of 178 mothers and their healthy full-term infants (n = 89 probiotic and n = 89 control). At 1 year of age, infants were clinically assessed for AD, food allergy and/or sensitisation. Potential confounders, such as differences in birth length and birth head circumference, antibiotic usage, play group attendance and daycare attendance, were considered in the final analyses. The conflicting results of this study in comparison to earlier findings may be due to many factors including differences in probiotics used, i.e. *Lactobacillus rhamnosus GG* compared to *L. acidophilus* LaVRI-A1, maternal diet regarding consumption of fermented foods, maternal and other family members at risk of AD, food allergy and/or sensitisation, differences in how the infants received the probiotic treatment and the time of the clinical measures.

In a recent double-blinded, placebo-controlled study by Kuitunen et al (2009), pregnant mothers (n = 1223) whose offspring were at increased risk for allergy were given either a probiotic mixture (2 lactobacilli, bifidobacteria and propionibacteria) (n = 610) or placebo during the last month of pregnancy (n = 613). After birth, the infants of the mothers who took probiotics also received the

probiotics with a prebiotic galacto-oligosaccharide for 6 months. The other infants received a placebo. After 5 years, the cumulative incidence of allergic diseases (eczema, food allergy, allergic rhinitis and asthma) and IgE sensitisation was determined in 891 (88%) infants (n = 445 in the intervention group, n = 446 in the control group). Perinatal probiotic supplementation did not confer any significant benefits in preventing allergy as there was little difference in any of these parameters, but interestingly, in caesarean-delivered children receiving probiotics, less IgE-associated allergic disease was reported (P = 0.035), indicating a protective effect.

High cholesterol

Some probiotics may have cholesterol-lowering effects due to several mechanisms including enzymatic deconjugation of bile acids and metabolic utilisation of cholesterol (Brashears et al 1998, Liong & Shah 2005).

According to a meta-analysis of six studies of a probiotic dairy product containing *Enterococcus faecium*, treatment with the fermented yoghurt product produced a 4% decrease in total cholesterol and a 5% decrease in low-density lipoprotein cholesterol (Agerholm-Larsen et al 2000).

Since then, mixed findings have been reported regarding the use of encapsulated probiotics; a hypocholesterolaemic effect was not observed in some studies (Lewis & Burmeister 2005, Larsen et al 2006, Simons et al 2006, Greany et al 2008, Hatakka et al 2008), but Hlivak et al (2005) provided a daily dose of 10^9 CFU of probiotic bacteria and noted a hypocholesterolaemic effect. It is possible that lipid-lowering activity induced by probiotics is dependent on whether patients have high cholesterol levels (>6.0 mmol/L) (Agerback et al 1995, Bertolami et al 1999, Hlivak et al 2005, Xiao et al 2003) or lower to normal cholesterol levels (<5.4 mmol/L) (de Roos et al 1999, Greany et al 2004), although further randomised trials are required to confirm this observation.

Most recently, two randomised, placebo-controlled studies failed to detect a significant lipid-lowering activity for different strains of probiotics. Greany et al (2008) conducted a randomised, single-blinded, placebo-controlled, parallel-arm study of 33 normocholesterolaemic women and 22 men aged 18–36 years. Subjects in the intervention group were treated for 3 months with probiotic capsules (3 capsules daily) containing a total of 10^9 CFU *Lactobacillus acidophilus* strain DDS-1 and *Bifidobacterium longum* strain UABL-14 and 10–15 mg fructo-oligosaccharide. These probiotic strains had no effect on plasma lipid concentrations (Greany et al 2008).

Likewise, Hatakka et al (2008) conducted a double-blind, randomised, placebo-controlled, two-period crossover study to investigate the effects of taking on a daily basis two probiotic capsules containing viable *Lactobacillus rhamnosus* LC705 and *Propionibacterium freudenreichii* ssp *shermanii* JS (2×10^{10}

Clinical note — The hygiene hypothesis

The intestinal tract is the largest immune organ of the body. It produces more antibodies than any other part of the body and contains 80% of all antibody-producing cells. The intestinal mucosa functions as a barrier against infections, but it also provides communication between the different mucosal surfaces of the body (Ouwehand et al 2002).

At birth, the gastrointestinal tract is sterile. Normal gut flora develops gradually over time and is influenced by factors such as composition of the maternal gut microflora, diet, degree of hygiene, use of antibiotics or other medication, the environment and possibly genetic aspects. Studies in germ-free mice have shown that without these bacteria, the systemic immune system will not function normally (Vanderhoof & Young 2002).

In the absence of microbes, a mammal develops fewer Peyer's patches (part of the gut-associated lymphoid tissue) and less than 10% of the number of IgA-producing B cells compared with normal. However, on exposure to a normal microflora, previously germ-free animals develop their immune system very much like other animals. This indicates that the intestinal microflora is instrumental in the proper development of the immune system (Ouwehand et al 2002) and has led to the emergence of the 'hygiene theory of immune disorders'.

More specifically, the hygiene hypothesis suggests that improved hygienic conditions and vaccinations, which reduce early-life exposure to microbes, are associated with a heightened risk of allergic disease and other immune disorders. This is because reduced exposure may result in reduced stimulation of the immune system. As a result, lymphocytes that would normally differentiate to become Th1 type differentiate to Th2-type cells and produce inflammatory cytokines in the allergic response in much greater quantities. As such, very early stimulation of the immune system is important in dampening the Th2 dominance and reducing the development of IgE-mediated food reactions as well as other allergic reactions. In a closely observed cohort of 329 Finnish children, it was shown that the earlier an acute respiratory infection occurred, the greater the protective effect was against atopic eczema (Vanderhoof & Young 2003).

The obvious solution for increasing microbial exposure without increasing the health risk is the use of prebiotics and probiotics. Supplementation with probiotics has been shown to both reduce the risk and treat the symptoms of childhood eczema (see later).

Modulating the intestinal microflora with probiotics and prebiotics (fibre) may be an effective and safe therapy for the natural development of a balanced immune defence in infants and children. In adults and the elderly, prebiotics and probiotics may be used to improve the general functioning of the immune system.

CFU of each strain) on serum cholesterol and triglyceride levels: the study of 38 mildly or moderately hypercholesterolaemic men aged 24–55 years found that probiotic treatment over 4 weeks did not have any effect on serum lipids.

Urogenital infections

Probiotics are widely used in active treatment of urogenital infections and to decrease the frequency of recurrent bacterial vaginosis and candidal vulvovaginitis. They are administered both orally and locally with several small trials supporting their use.

Recent studies using molecular typing have confirmed that oral intake of probiotics results in vaginal colonisation (Reid & Bruce 2006). This confirms findings from previous studies which have also shown that oral administration of lactobacilli results in colonisation of the gastrointestinal and the genitourinary tract.

A daily dose of 10^9 viable *Lactobacillus* GR-1 and RC-14 bacteria in 10 women with repeated bacterial vaginosis, yeast infections and/or urinary tract infections (UTIs) resulted in resolution of symptoms in most of the women. Symptoms abated within a fortnight, and all the patients remained healthy for several months following treatment (Reid et al 2001). The same authors reported an enhanced effect of *L. rhamnosus* GR-1 and *L. fermentum* RC-14 administered orally, resulting in rapid vaginal colonisation within 7 days (Reid et al 2001), and even after treatment cessation, there were still some women where this remained to be the case.

Consumption of a yoghurt containing *L. acidophilus* for 1 year by women with recurrent vaginitis resulted in a reduced colonisation by *Candida* infection (Hilton et al 1992).

Other studies have also reported local application or oral ingestion of probiotic lactobacilli and bifidobacteria in vulvovaginitis (Falagas et al 2006) and UTIs (Borchert et al 2008), but there is a need for larger, randomised, controlled, clinical trials to investigate and confirm these effects.

The mechanisms by which *Lactobacillus* spp reduce bacterial vaginosis and UTIs appear to involve antiadhesion factors, byproducts such as hydrogen peroxide and bacteriocins lethal to pathogens and perhaps immune modulation or signalling effects. Bifidobacteria in particular are considered well suited to this activity and have, therefore, been investigated for their effects in the treatment of female genitourinary infections (Korshunov et al 1999).

Additionally, lactobacilli play a significant role in the prevention of UTIs. Studies using intravaginal administration of probiotics such as *Lactobacillus* GR-1 and B-54 or RC-14 strains have demonstrated that treatment resulted in fewer UTIs than placebo and improved the maintenance of normal flora (Reid & Bruce 2006). A significant reduction in UTI rate was also reported in a randomised double-blind study involving 55 premenopausal women (Reid 2001). The study investigated the effectiveness of treatment for 1 year with a weekly suppository containing either 0.5 g *L. rhamnosus* GR-1 and *L. fermentum* B-54 or a *Lactobacillus* growth factor. Treatment resulted in the UTI rate decreasing by 73% and 79%, respectively, with no adverse effects reported.

> ***Clinical note — Dosages tailored to increase probiotic survival***
> Enteric-coated tablets containing probiotics that are gastric acid resistant have been produced (Stadler & Viernstein 2003). More studies, however, are needed to examine the efficacy of these administration forms to deliver and release the probiotic at the appropriate target sites in the gastrointestinal tract.

OTHER USES

Probiotics may have many potentially important clinical applications, and current areas of active research include mostly animal studies investigating a range of diseases including control or prevention of cancer (Fotiadis et al 2008) and prevention or treatment of graft-versus-host disease in transplant recipients (Gerbitz et al 2004).

DOSAGE RANGE

Probiotic doses are usually standardised in terms of the amount of living bacteria per unit of volume. A quality product may contain between 1×10^9 and 1×10^{11} CFU/g; however, the dose required to achieve therapeutic effects varies between strains. If a product contains multiple strains, then each strain should be present at levels of 10^9 to be effective. The viable bacteria are mixed in a suitable matrix, which may contain maltodextrin, amylase and prebiotics such as fructo-oligosaccharides and inulin.

As more information is gathered from probiotic research, it is becoming evident that certain strains or a combination of strains is suitable for different conditions. Different strains of probiotics are chosen and combined to produce specific products for diarrhoea in children, antibiotic induced diarrhoea, travellers' diarrhoea, IBDs etc.

Supplements are best taken with meals to enhance bacterial survival.

A serving of yoghurt containing fewer than 10^8 viable bacteria is unlikely to have any therapeutic activity beyond acting as a nutritional source.

ADVERSE REACTIONS

Probiotics are generally regarded as safe. However, probiotic therapy should be used with caution in the young, elderly and those with immunocompromised function as they may be at increased risk of adverse reactions. Infections, sepsis and meningitis have been reported in adult cases when administered lactobacilli (Land et al 2005, Mackay et al 1999, Rautio et al 1999). Cases of young children and infants have also been reported (Borriello et al 2003).

Oral administration of *S. boulardii* has resulted in fungaemia in 50 patients (Enache-Angoulvant & Hennequin 2005). There is also concern in

critically ill patients because impaired intestinal barrier function could result in infection as a result of bacterial translocation (Land et al 2005, Munoz et al 2005). Recently, there have been reports about increased mortality in patients with severe acute pancreatitis who were administered a multispecies probiotic (Besselink et al 2008).

SIGNIFICANT INTERACTIONS

Antibiotics

Concomitant administration of some strains of probiotics reduces gastrointestinal and genitourinary side effects according to clinical studies — combination can be safely used together and a beneficial interaction is likely.

CONTRAINDICATIONS AND PRECAUTIONS

Specific strains of probiotics are appropriate for different disorders. Probiotics are contraindicated in those people who are hypersensitive to any component of the probiotics-containing product.

PREGNANCY USE

Likely to be safe in pregnancy; however, use of concentrated forms should be supervised by a healthcare professional.

PATIENTS' FAQs

What can probiotics do for me?

Studies have shown that probiotics are beneficial in the treatment of digestive disorders such as diarrhoea and some IBDs and also other conditions not directly connected with the digestive tract, such as vaginal thrush and recurrent cystitis, antibiotic induced and travellers' diarrhoea, IBS, food allergies and eczema.

When will they start to work?

Usually, probiotics can exert beneficial effects in digestive disorders within days although continuous use for several weeks/months may produce long-term benefits and be necessary in the treatment of other disorders.

Are there any safety issues?

Generally, probiotics have a good safety profile; however, high-dose supplements should be used under supervision by the very young, elderly and immunocompromised.

PRACTICE POINTS/PATIENT COUNSELLING

- Although probiotics may improve the long-term bowel flora, probiotic supplementation has many other benefits not associated with direct colonisation of the gastrointestinal tract.
- Studies have shown that probiotics are beneficial in the treatment of digestive disorders such as diarrhoea and some IBDs and also other conditions, such as urogenital infections, antibiotic induced and travellers' diarrhoea, IBS, food allergies, eczema and the prevention and treatment of paediatric AD.
- There is also some evidence that probiotics are essential for both the development and the maintenance of a healthy immune system.
- Probiotics can be administered orally or intravaginally. They can also be taken as yoghurt or other cultured dairy products. It should be noted that only products containing actual probiotic strains will be beneficial. The so-called starter cultures do not necessarily have the same beneficial effects.
- For travellers' diarrhoea, it is recommended that the probiotic dose be started some days before travelling to ensure that the beneficial bacteria have colonised the gut; the dosage may vary depending on the probiotic strain.

Psyllium

HISTORICAL NOTE Psyllium has a long history of use in both conventional and traditional medical systems and has been listed in various pharmacopoeias around the world.

OTHER NAMES

Psyllium seed, Blonde *Plantaginis ovatae* semen — ripe seeds of *Plantago ovata* (*P. isphagula*).

Plantago ovata semen refers to the unprocessed seed.

White or *blond* psyllium, also known as Indian plantago.

Psyllium seed husk, Blonde *Plantaginis ovatae testa* — referring to the epidermis layers of *Plantago ovata* (*P. isphagula*)

Psyllium seed, Black *Psyllii semen* – referring to the dried ripe seed of *Plantago psyllium* (*P. afra*, *P. arenaria* and *P. indica*)

Black, French or Spanish psyllium comes from *P. psyllium* (syn. *P. afra*) and *P. arenaria* (*P. indica*).

Psyllium seed husk is generally sold over the counter as Metamucil®.

BOTANICAL NAME/FAMILY

Plantago ovata, *P. psyllium*, *P. arenaria* (family Plantago)

PLANT PART USED

Seed coat and seed

CHEMICAL COMPONENTS

Plantago ovata seed husk generally consists of 67–71% fibre, constituents includes 10–30% mucilage (arabinoxylans), iridoid glycosides (≈ aucubin), trace monoterpene alkaloids, sugars, protein, sterols, triterpenes, fatty acids and tannins. Phytosterol and beta-sitosterol (Nakamura et al 2005).

MAIN ACTIONS

Bulking agent

Psyllium husk is commonly used throughout the world as a bulking agent in the treatment of both constipation and diarrhoea. A component of psyllium husk is incompletely fermented, forming a mucilaginous gel which provides lubrication, increases moisture content and facilitates propulsion of the colon contents (Marlett et al 2000).

Psyllium promotes stools that are more frequent and softened, and reduces pain on defecation. Psyllium has been shown to be more beneficial in maintaining regularity than bran (Singh 2007).

Promotes satiety

A placebo-controlled study of a *P. ovata* preparation administered in water found a significant difference in satiety 1 h after consumption (Turnbull & Thomas 1995). Increased satiety was apparent up to 6 h after consumption. A recent animal study showed that amongst its proposed range of action psyllium had the potential to attenuate weight gain (Wang et al 2007).

Lipid lowering

Psyllium husk effectively reduces lipid levels by altering cholesterol metabolism, increasing hepatic cholesterol catabolism and increasing faecal bile acid excretion (Romero et al 2002). *Psyllium* sequesters bile salts during passage through the intestinal lumen as well as physically disrupts the intraluminal formation of micelles, thereby reducing the absorption of cholesterol and re-absorption of bile salts. As a result, bound bile acids are moved to the terminal ileum and colon, thereby interrupting the enterohepatic circulation so that more cholesterol is converted into newly produced bile acids (Rodriguez-Moran et al 1998). It is postulated that this increased hepatic conversion of cholesterol into bile acids results in increased LDL uptake by the liver, leading to decreased levels of serum LDL cholesterol and total cholesterol (Theuwissen & Mensink 2008). Reduced cholesterol biosynthesis results in an upregulation of LDL receptors and enhanced uptake of LDL cholesterol (Shrestha et al 2007). Both the unfermented and viscous components of psyllium are considered responsible for the observed lipid-lowering effects (Marlett & Fischer 2003, Dikeman & Fahey 2006).

Slows glucose absorption

Animal and human models have demonstrated that psyllium modulates the glycaemic response through various mechanisms. Psyllium supplementation delays gastric emptying, small bowel motility and reduces intestinal mixing, thereby slowing and reducing glucose absorption across the intestinal lumen of the small intestine (Dikeman & Fahey 2006). Psyllium has induced an upregulation of GLUT-4 receptors in skeletal muscle cell membranes in vitro (Song et al 2000) and has been shown to improve glycaemic response by modulating postprandial glucose concentrations and insulin

requirements (Anderson et al 1999, Frati-Munari et al 1989, Sierra et al 2001).Wang et al demonstrated in vivo that psyllium enhances insulin sensitivity, reduces weight gain and modulates GLP-1 secretion (Wang et al 2007).

CLINICAL USE

Psyllium is used mainly for its mucilage content, which comes from the seed coat.

Bulking agent

Psyllium is commonly used as a bulking agent to treat constipation or diarrhoea and to regulate stool consistency in people with a colostomy or ileostomy. As a bowel regulator, psyllium husk absorbs water in the colon to increase faecal bulk, which stimulates peristaltic activity. Alternatively, psyllium can be used to promote normal stool formation in people with diarrhoea by decreasing the frequency of fluid stools. Commission E approves the use of black psyllium seed and blond psyllium seed for chronic constipation and when a soft stool is desirable, such as in patients with haemorrhoids, anal fissures or postrectal surgery (Blumenthal et al 2000).

The symptoms associated with constipation-induced haemorrhoids may also be reduced through administration of psyllium. A reduction of pain and length of hospital stay following open haemorrhoidectomy were achieved through supplementation of laxomucil (3.26 g psyllium) (Kecmanovic et al 2004). A subsequent study further identified a reduction of postsurgical tenesmus rate (Kecmanovic et al 2006).

Weight loss aid

Psyllium is used to increase the subjective feeling of satiety before and between meals in an attempt to reduce total caloric intake. One study comparing *Plantago ovata* preparation (20 g granules with 200 mL water) to water or a placebo preparation found a significant difference in fullness 1 h after consumption (Turnbull & Thomas 1995). Other studies have confirmed a suppressant effect on hunger and increased satiety that remains apparent up to 6 h after consumption. Psyllium also significantly delays gastric emptying from the third hour after a meal (Bergmann et al 1992, Delargy et al 1997).

Hyperlipidaemia

Psyllium is also used as a cholesterol-lowering agent, usually as an adjunct to a low-fat diet (Reid et al 2002). Soluble fibres, such as psyllium husk, increase the cholesterol-lowering effect of a low-fat diet in people with elevated cholesterol (Anderson et al 2000). A meta-analysis of 21 controlled clinical trials (n = 1697) testing psyllium dosages ranging between 3.0 and 20.4 g daily confirmed that psyllium produced a time- and dose-dependent serum cholesterol-lowering effect in patients with mild-to-moderate hypercholesterolaemia (Wei et al 2009). Reductions in serum cholesterol occurred more quickly than changes in LDL cholesterol with psyllium supplementation.

Similar results were obtained in two previously published meta-analyses. Davidson et al (1996) evaluated data from eight studies and found that psyllium (10.2 g/day) lowered serum total cholesterol by 4%, LDL cholesterol by 7% and the ratio of apolipoprotein (apo) B to apo A–I by 6% relative to placebo. This was achieved together with a low-fat diet over 8 weeks. It has also been used with some success in the paediatric population and is easy to incorporate into various foods (Davidson et al 1996). Olson et al (1997), using the data from 404 subjects with mild-to-moderate hypercholesterolaemia concomitantly consuming a high-fat diet supplemented with psyllium in the form of cereal, found psyllium to be beneficial in lowering both LDL and total cholesterols; however, HDL concentrations were unaffected (Olson et al 1997).

Studies with statin drugs

A 12-week blinded, placebo-controlled study comprising 68 patients demonstrated that supplementation of dietary psyllium 15 g (Metamucil®) daily in patients taking 10 mg of simvastatin was as effective in lowering cholesterol as 20 mg of simvastatin alone (Moreyra et al 2005). However, a 4-week open label, randomised, parallel study of 36 subjects demonstrated that 10 g of psyllium daily added to 20 mg of lovastatin provided an additive effect in cholesterol lowering than lovastatin alone, although the difference was not statistically significant (Agrawal et al 2007). The duration of the supplementation may offer some insight into conflicting outcomes. In a 12-week study involving 100 subjects with hyperlipidaemia randomised to receive either a combination of isapgol powder (Naturolax) 5.6 g twice daily and atorvastatin 10 mg once daily or atorvastatin 10 mg daily alone, significant reduction in LDL cholesterol was achieved at the end of week 8; there was, however, no difference between treatment groups. However, at the end of week 12, the combination of isapgol and atorvastatin produced significantly greater reduction in LDL when compared to atorvastatin alone (Jayaram et al 2007).

Diabetes

Fibre products, such as psyllium, have been used as an aid to metabolic control in patients with diabetes (Pittler & Ernst 2004, Sierra et al 2002). Epidemiological and clinical data suggest a role for both soluble and insoluble fibre products in the management of hyperglycaemia. It appears that soluble fibre has a dose-dependent effect on serum glucose levels and the insulin response to a meal, improves glycaemic control in type 2 diabetes and can reduce the amount of medication required (Pastors et al 1991).

The adjunct use of 5.1 g psyllium twice daily for 8 weeks with a traditional diet for 34 men with type 2 diabetes and mild-to-moderate hypercholesterolaemia was well tolerated and shown to improve glycaemic and lipid levels as compared to placebo (Anderson et al 1999). One clinical study using 14 g/day of psyllium (Plantaben, ALTANA Pharma, Mexico) showed a significant 12.2% reduction in glucose absorption, as well as a significant reduction

in total cholesterol and LDL cholesterol, and also uric acid (Sierra et al 2002). Another study identified that a higher dose (20 g/day in divided doses) may produce better results and significantly lowers both basal and postprandial hyperglycaemia (Frati-Munari et al 1989). In an 8-week double-blind, placebo-controlled study of 49 subjects, psyllium (5.1 g twice daily) was evaluated as an adjunct to the use of diet and pharmaceutical hypoglycaemic therapy in patients with type 2 diabetes. Fasting blood glucose and glycosylated haemoglobin were significantly reduced following psyllium administration and improved gastric tolerance to metformin was identified in the psyllium group. The authors concluded psyllium to be safe, well tolerated and improved glycaemic control in patients with type 2 diabetes (Ziai et al 2005). Psyllium significantly improved the breakfast postprandial glycaemic, insulinemic and free fatty acid response in 45 patients with type 2 diabetes mellitus participating in a randomised, crossover intervention trial of a low-glycaemic load breakfast meal containing soluble psyllium fibre 6.6 g for 3 weeks duration (Clark et al 2006).

Irritable bowel syndrome (IBS)

In IBS with constipation predominant symptoms, soluble fibres, including psyllium, have been found to be more effective than insoluble fibres in relieving symptoms and reducing constipation (Chang et al 2006); however, fibre is not considered to be effective in improving abdominal pain, bloating or distension (Fernandez-Banares 1999). Black and blond psyllium seed is approved for use by Commission E in IBS and recommended when a soft stool is desired (Blumenthal et al 2000).

Inflammatory bowel disease

A limited number of studies have examined the ability of psyllium to maintain remission in ulcerative colitis. A randomised controlled trial of 120 patients with ulcerative colitis demonstrated that patients receiving treatment with a symbiotic therapy of *Bifidobacterium longum* (2×10^9 colony-forming units, 1 daily) and psyllium (8 g daily) reported greater 'quality-of-life' changes than those treated with probiotic or psyllium alone (Fujimori et al 2009).

Hypertension

Participants in a randomised controlled trial of 41 hypertensive patients increased their intake of dietary protein and psyllium (additional 12 g/day) for 8 weeks. A net reduction in 24-h systolic blood pressure of 5.9 mmHg was demonstrated (Burke et al 2001). In a 6-month, randomised, open-label clinical trial involving 141 hypertensive and overweight patients, treatment with psyllium powder as compared to guar gum appeared to significantly reduce systolic and diastolic blood pressures (Cicero et al 2007).

OTHER USES

In the confectionery industry, it is used as a thickening agent in ice cream and frozen desserts.

DOSAGE RANGE

General recommendations

- Blond psyllium seed: 12–40 g of whole seeds or equivalent taken in divided doses daily.
- Black psyllium seed: 10–30 g of whole or ground seeds or equivalent taken in divided doses daily.

Seeds should be presoaked in 100–150 mL of warm water for several hours before ingestion. Each dose should be followed by another full glass of water.

- Powdered blond psyllium seed husk: 4–5 g taken up to four times daily. Stir desired dose into 150 mL of water and drink immediately. Follow each dose with ½–1 glass of water.

According to clinical studies

- Weight loss: *Plantago ovata* preparation (20 g granules with 200 mL water).
- Constipation: 7–11 g daily in divided doses with water.
- Hyperlipidaemia: 7–20 g daily in divided doses with water.
- Hyperglycaemia: 10–15 g daily in divided doses with water.
- Diabetes: 14–20 g daily in divided doses.
- Diarrhoea: 7–30 g in divided doses for 7 days with water.
- Haemorrhoids: 7 g daily for 6 weeks with water.
- Children 6–12 years: 3–8 g in divided doses.

SIGNIFICANT INTERACTIONS

Calcium

Animal studies suggest that soluble fibre from sources of purified psyllium negatively impact calcium balance by decreasing the bioavailability of calcium from the diet (Luccia & Kunkel 2002) — psyllium and other soluble fibre supplements should be taken at least 1 h before or after calcium.

Lithium

Soluble fibre may decrease the bioavailability of lithium (EMEA 2003) — take psyllium at least 1 h before or after lithium.

Coumarin derivatives

Soluble fibre may decrease the bioavailability of coumarin derivatives (EMEA 2003) — take psyllium at least 1 h before or after coumarin derivatives.

Vitamin B_{12}

Soluble fibre may decrease the bioavailability of vitamin B_{12} (EMEA 2003) — take psyllium at least 1 h before or after vitamin B_{12}.

Cardiac glycosides

Soluble fibre may decrease the bioavailability of cardiac glycosides (EMEA 2003) — take psyllium at least 1 h before or after cardiac glycosides.

Hypoglycaemic agents

Additive hypoglycaemic effects are theoretically possible — drug dose may need modification and

the outcome can be favourable under professional supervision.

Anticonvulsant medication
Absorption concomitantly administered with psyllium may be delayed (EMEA 2007) — product taken one hour to half an hour before or after the medicinal product.

Thyroid hormones
Medication dose may need to be adjusted — seek medical supervision (EMEA 2007).

Lipid lowering agents
Concomitant use of psyllium with lipid-lowering drugs may lead to a reduction in drug dose and further lipid-lowering effects — beneficial interaction.

ADVERSE REACTIONS
Allergy is possible, although rare and is characterised by tightness in the chest, wheezing and urticaria. According to a study of healthcare workers, daily exposure to laxatives containing plantago ovata causes sensitisation to plantago ovata seed in approximately 14% of people (Bernedo et al 2008). Psyllium should not be consumed dry, as it may cause oesophageal obstruction. In practice, it is not unusual for people to experience flatulence, bloating and mild abdominal discomfort when they start to use psyllium; however, these symptoms can reduce with long-term use.

CONTRAINDICATIONS AND PRECAUTIONS
Although psyllium is considered a safe substance, it should not be used by people with partial or complete bowel obstruction, colonic impaction or stenosis of the gastrointestinal tract.

According to Commission E, blond psyllium seed is contraindicated if there is difficulty regulating diabetes mellitus.

PREGNANCY USE
May be used during pregnancy and lactation.

PRACTICE POINTS/PATIENT COUNSELLING
- Psyllium seed husk is a water-soluble fibre that forms a mucilaginous gel on contact with aqueous fluids and is degraded by human intestinal flora.
- It is most commonly used to treat constipation or diarrhoea and to regulate stool consistency.
- It is also used to promote satiety and weight loss, and as an aid to metabolic control in diabetes and hyperlipidaemia when combined with a low-fat diet.
- The seeds should be presoaked in warm water for several hours before ingestion and each dose should be followed by a full glass of water. Ingesting it dry may cause oesophageal obstruction.
- Although generally safe, it should not be used by people with partial or complete bowel obstruction, colonic impaction or stenosis of the gastrointestinal tract.

PATIENTS' FAQs
What will this herb do for me?
Psyllium is a bulking agent that can regulate stool consistency, increase satiety, improve metabolic control in diabetes and reduce cholesterol when combined with a low-fat diet.

When will it start to work?
As a bulking agent, it will start to have an effect within several hours. It will improve satiety within 30–60 min and has a mild cholesterol-lowering effect after 8 weeks of use.

Are there any safety issues?
Although generally safe, it should not be ingested dry or used by people with partial or complete bowel obstruction, colonic impaction or stenosis of the gastrointestinal tract.

Pygeum

HISTORICAL NOTE *Pygeum africanum* is a large, evergreen tree native to Africa. Its bark has been used medicinally for thousands of years by traditional African healers to treat bladder disorders, kidney disease, prostate disorders and malaria, as well as male baldness and to enhance sexual functioning. Since the late 1960s, the extract has been used in clinical practice in Europe; however, because of overharvesting, the plant is now considered an endangered species and efforts are underway to protect it.

COMMON NAME
Pygeum

OTHER NAMES
African plum tree, African prune tree, *Pygeum africanum*, alumty, iluo, kirah, Natal tree, Pignil®, Pronitol®, Tanaden®

BOTANICAL NAME/FAMILY
Prunus africana (Hook. f.) KalRm (family Rosaceae)

PLANT PART USED
Bark

CHEMICAL COMPONENTS
Phytosterols (beta-sitosterol, beta-sitostenone), pentacyclic triterpenes (oleanolic and ursolic acids) and ferulic esters (*n*-docosanol and *n*-tetracosanol) (Stewart 2003) and atraric acid and benzoic acid (Schleich et al 2006).

Clinical note — Popular to the point of extinction?
For the past 35 years, pygeum has been used in Europe for the treatment of benign prostatic hyperplasia (BPH) and other disorders. The bark is entirely wild collected, mainly from Cameroon, Madagascar, Equatorial Guinea and Kenya, and exported principally to Europe for production into commercial medicinal extracts (Stewart 2003). Since 1995, it has been considered an endangered species, so attempts at cultivation are underway to protect the plant from extinction. Prior to 1966 when it was discovered to have significant medicinal effects, *P. africana* was a relatively common but never abundant species. The reasons for its demise include economic, social and ecological factors. Currently, wildcrafting is no longer commercially viable in Cameroon, and harvest has ceased in both Uganda and Kenya.

MAIN ACTIONS

Pygeum has demonstrated several different pharmacological effects according to in-vitro and in-vivo data. The majority of initial studies conducted on *P. africanum* were investigating its role in the symptomatic relief of BPH. More recent research is seeking to elucidate pygeum's pharmacological capacity in the modulation and restoration of bladder function, androgen receptor modification and attenuating prostatic cancer cell line replication.

Hormonal effects

In-vivo studies have shown that orally administered pygeum extract has a significant effect on dihydrotestosterone (DHT)-induced prostatic enlargement (Choo et al 2000, Yoshimura et al 2003). Pretreatment with pygeum extract counteracted the effect of DHT-induced prostate enlargement (Choo et al 2000), and the more recent study found that oral administration of pygeum extract suppressed the effects of DHT on micturition (Yoshimura et al 2003) and effectively suppressed prostatic growth when coadministered with DHT; however, it did not reverse established prostatic growth when administered after DHT. A comparative study found that pygeum exerted only a weak inhibition of 5-alpha reductase compared to that of finasteride (Rhodes et al 1993). Phyto-oestrogens isolated in pygeum can exert a dose-dependent oestrogenic or anti-oestrogenic effect, according to other in-vivo tests (Mathe et al 1995), and may also contribute to its effects in the prostate.

Antiandrogenic

Recent in-vitro investigations have confirmed the antiandrogenic activity of pygeum. When compared to *Serenoa repens* and *Cucurbita pepo*, pygeum exhibited the highest androgen antagonistic activity (Schleich et al 2006). Atraric acid, isolated from pygeum, has been shown to selectively inhibit transactivation-mediated ligand-activated human androgen receptor, inhibiting the expression of endogenous prostate-specific antigen (Schleich et al 2006).

Anti-inflammatory

Phytosterols (beta-sitosterol, beta-sitostenone) reportedly inhibit the production of prostaglandins in the prostate, which suppresses the inflammatory symptoms associated with BPH and chronic prostatitis. The pentacyclic triterpenes (oleanolic and ursolic acids) are believed to inhibit the activity of glucosyltransferase, an enzyme involved in the inflammation process (Stewart 2003).

Studies with pygeum extract confirm that it decreases production of leukotrienes and other 5-lipoxygenase metabolites (Cristoni et al 2000).

Bladder effects

Pygeum protects the bladder from contractile dysfunction induced by ischaemia and reperfusion according to in-vivo animal studies (Chen et al 1999). Pretreatment with pygeum prior to induced partial outlet obstruction in animal models prevents the development of contractile dysfunction, possibly by protecting the bladder from ischaemic injury (Levin et al 2005). Administration of pygeum was found to reverse already ischaemic compromised bladder function in a dose-dependent manner (Levin et al 2002).

Inhibition of fibroblast proliferation

Pygeum is a potent inhibitor of prostatic growth factor-mediated fibroblast proliferation, as demonstrated in animal models (Yablonsky et al 1997, Szolnoki et al 2001). A dose-dependent inhibition of fibroblastic growth was exerted in human stromal cells treated with pygeum extract (Boulbes et al 2006).

Chemopreventative

Recent investigations have focused primarily upon *P. africanum* regulation of cancer cell growth in vitro and in vivo. Treatment with pygeum extract exhibited a significant and dose-dependent inhibition of human prostate cancer cell lines and BPH-derived epithelial cells. Pygeum also exerted a potent antimitogenic action in this study (Santa Maria Margalef et al 2003). Pygeum-treated mice displayed a significant reduction in prostate cancer incidence (35%) in comparison to the casein-fed mice (62.5%) (Shenouda et al 2007).

OTHER ACTIONS

Ferulic esters (*n*-docosanol and *n*-tetracosanol) reportedly lower blood levels of cholesterol, from which testosterone is produced (Stewart 2003).

CLINICAL USE

The most commonly investigated form of *P. africanum* is Tanenan® (DEBAT pharmaceuticals, France), which is a lipophilic extract standardised to contain 13% total plant sterols. One capsule of Tadenan® contains 50 mg of standardised extract.

Benign prostatic hyperplasia (BPH)

Clinical trials since the late 1970s have been encouraging, most reporting improvement in BPH symptoms.

A Cochrane systematic review analysed the results of 18 clinical trials that involved a total of 1562 participants (Wilt et al 2002). Seventeen studies were double blinded, and the mean treatment duration was 61 ± 21 days (range 30–122 days). Most studies used a standardised extract of *P. africanum* in doses ranging from 75 to 200 mg/day.

The overall summary effect size indicated a large and statistically significant improvement with *P. africanum*. More specifically, active treatment increased peak urine flow by 23% and reduced residual urine volume by 24%, and physicians were twice as likely to report that their patients were experiencing an overall improvement in symptoms when pygeum was being used. The authors report that these findings are similar to other widely used treatment options and that treatment was well tolerated.

It is believed that the phytosterols, pentacyclic triterpenes and ferulic esters found within the extract work synergistically to counteract the structural and biochemical changes associated with BPH.

A systematic review of clinical trials for the use of phytotherapy in the treatment of lower urinary tract symptoms secondary to BPH concluded that pygeum improved flow rates and symptoms compared to placebo (Dedhia & McVary 2008). A prior critical review of pygeum highlighted the difficulty in establishing concise clinical efficacy of pygeum in BPH owing to poorly designed trials of limited duration and high placebo response. Researchers suggested the need for large-scale clinical trials (Edgar et al 2007).

OTHER USES

Fertility disorders

Pygeum extract was used experimentally in the treatment of 22 men with reduced fertility and diminished prostatic secretion and proved to have a beneficial effect (Lucchetta et al 1984). Treatment was administered every day over 2 months and was most effective in men who did not have prostatitis.

DOSAGE RANGE

According to clinical studies

- BPH: 50–100 mg of extract twice daily standardised to 12–13% total sterols

ADVERSE REACTIONS

Pygeum is well tolerated with side effects similar to placebo (Wilt et al 2002). Mild gastrointestinal discomfort has been reported.

SIGNIFICANT INTERACTIONS

None known.

CONTRAINDICATIONS AND PRECAUTIONS

People with known allergies should avoid use.

PREGNANCY USE

Safety not scientifically established; however, it is not used for any indication that would cause a pregnant woman to use it.

PRACTICE POINTS/PATIENT COUNSELLING

- Pygeum is a popular treatment in Europe for BPH.
- A systematic review of 18 clinical studies found that it has significant effects in BPH such as increasing peak urine, reducing residual urine volume and producing an overall improvement in symptoms.
- Several different mechanisms of action have been identified using animal models, which would explain its effectiveness in BPH.
- According to clinical studies, the dose used is 50–100 mg of standardised extract twice daily for BPH and the treatment is well tolerated.
- Overharvesting has meant the tree is now considered endangered and efforts are being made to protect it from extinction.

PATIENTS' FAQs

What will this herb do for me?

Standardised pygeum extract is an effective treatment in benign prostate enlargement or inflammation and improves several symptoms.

When will it start to work?

Some men will notice an improvement in symptoms after 4 weeks; however, others will require a long-term treatment.

Are there any safety issues?

It is a well-tolerated treatment but should not be used by people with a known allergy to the plant. If symptoms worsen, seek professional advice.

Quercetin

BACKGROUND AND RELEVANT PHARMACOKINETICS

Quercetin is a flavonol belonging to a group of polyphenolic substances known as flavonoids or bioflavonoids. The first flavonoids were identified in 1936 by Albert Szent-Györgyi, who was awarded the Nobel Prize for his discovery of vitamin C (Challem 1998).

Studies on the absorption, bioavailability and metabolism of quercetin after oral intake in humans have produced contradictory results (Graefe et al 1999). The nature of quercetin metabolites in plasma is currently unclear and requires further elucidation (Day & Williamson 2001), which may in part explain these inconsistencies.

In recent human trials, supplementation increased plasma quercetin concentrations in a dose-dependent manner: 178% (50 mg), 359% (100 mg) and 570% (150 mg); and maximum plasma concentrations were reached 6 h after intake of a 150-mg dose. There was also a significant variation between individuals for plasma quercetin concentrations (36–57%) (Egert et al 2008). Factors that may improve bioavailability include gender (especially females taking oral contraceptives), gastrointestinal flora (Erlund 2004) and concurrent intake of bromelain and papain (Shoskes et al 1999). Absorption from onions is three times that of apples (Hollman et al 1997) and twice that of black tea (deVries et al 1998).

The main determinant for the absorption of quercetin conjugates is the nature of the sugar moiety. Glucose-bound glycosides (quercetin glucosides) are effectively absorbed from the small intestine because the cells possess glucoside-hydrolysing activity and their glucose transport system is capable of participating in glucoside absorption, whereas quercetin glycosides are subject to deglycosidation by enterobacteria before absorption in the large intestine (Murota & Terao 2003).

After absorption, quercetin is transported to the liver via the portal circulation, where it undergoes significant first-pass metabolism. Peak plasma levels of quercetin occur from 0.7 to 9 h following ingestion, and the elimination half-life of quercetin is approximately 23–28 h (Hollman et al 1997, PDRHealth 2005). Due to its long half-life, repeated consumption of quercetin-containing foods should cause accumulation of quercetin in the body. Excretion is likely to be via the biliary system (Erlund 2004).

CHEMICAL COMPONENTS

Quercetin, also known as meletin and sophretin, is known chemically as 2-(3,4-dihydroxyphenyl)-3,5,7-trihydroxy-4H-1-benzopyran-4-one and 3,3′,4′5,7-penthydroxyflavone. It is typically found in plants as a glycone or carbohydrate conjugate but does not in itself possess a carbohydrate moiety in its structure. Quercetin glycone conjugates include rutin (quercetin-3-rutinoside) and quercitrin (thujin, quercetin-3-L-rhamnoside or 3-rhamnosylquercetin) (Erlund et al 2000, PDRHealth 2005).

FOOD SOURCES

Apples, berries (blackcurrants, lingonberries and bilberries), beans, black tea, broccoli, grapes, green tea, onions and red wine (Somerset & Johannot 2008)

Herbal medicines such as St John's wort, *Ginkgo biloba*, *Vaccinium macrocarpon* (cranberry) and *Oenothera biennis* (evening primrose) also contain quercetin and this may help to explain some of their therapeutic benefits.

MAIN ACTIONS

Antioxidant/pro-oxidant

Quercetin is a phenolic antioxidant and has been shown to inhibit lipid peroxidation, protecting the lens of the eye (Cornish et al 2002) and renal tubular epithelial cells from oxidant-induced injury (Pietruck et al 2003). The antioxidant activity may be the result of free radical scavenging, metal chelation, enzyme inhibition or the induction of protective enzymes (Erlund 2004). In addition, while quercetin does not appear to significantly affect the elevation of intracellular calcium concentration that results from oxidative stress, it does appear to greatly delay the process of calcium-dependent cell death that usually follows (Sakanashi et al 2008).

While some studies demonstrate that quercetin treatment at low concentrations or for short periods may exert an antioxidant effect, other trials suggest that higher concentrations or long-term treatment may produce a pro-oxidant effect (Robaszkiewicz et al 2007, Ferraresi et al 2005). These effects may be due to induction of oxidative stress due to formation of reactive oxygen species in the extracellular medium (Robaszkiewicz et al 2007) or increasing oxidant activity due to a reduction in glutathione (GSH) levels (Ferraresi et al 2005). The paradox is that in the process of offering protection, quercetin depletes GSH levels and is converted into potentially toxic products (thiol-reactive quercetin metabolites) (Boots et al 2007). In the absence of GSH, potentially harmful oxidation products such as orthoquinone may be produced when quercetin exerts its antioxidant activity. Therefore, adequate GSH levels should be maintained when quercetin is supplemented (Boots et al 2003).

In recent human trials, while daily supplementation of quercetin (50, 100 and 150 mg/day) for 2 weeks dose-dependently increased plasma quercetin concentrations, it did not appear to affect antioxidant status, oxidised low density lipoprotein (LDL), inflammation or metabolism (Egert et al 2008). Furthermore, in a placebo-controlled

trial of 40 athletes, chronic quercetin ingestion (1000 mg/day) for 6 weeks was not able to exert protection from exercise-induced oxidative stress and inflammation (McAnulty et al 2008).

Anti-inflammatory

In animal and in-vitro studies, quercetin inhibits inflammation by modulating neutrophil function, prostanoid synthesis, cytokine production and iNOS expression via the inhibition of the neutrophil factor (NF)-kappa-B pathway (Busse et al 1984, Comalada et al 2005, Morikawa et al 2003). While quercetin supplementation has been shown to decrease circulating markers of inflammation in mice (Stewart et al 2008), these effects have not been replicated in humans (Egert et al 2008, McAnulty et al 2008).

Antiviral

Quercetin causes a dose-dependent reduction in the infectivity and intracellular replication of herpes simplex virus (HSV)-1, poliovirus type 1, parainfluenza virus type 3 and respiratory syncytial virus in vitro (Kaul et al 1985); however, pretreatment with quercetin does not appear to provide any additional benefit. Animal studies have also suggested that the antioxidant effects of quercetin may protect the lungs from the deleterious effects of oxygen-derived free radicals released during influenza infection (Kumar et al 2005).

Immunomodulation

Results from animal and in-vitro studies have produced contradictory results, suggesting both an induction and an inhibition of Th1 cytokines (Muthian & Bright 2004, Nair et al 2002).

According to in-vitro data, quercetin induces Th1-derived cytokines (promoting cellular immunity) and inhibits Th2-derived cytokines, which exert negative effects on cellular immunity (Nair et al 2002). An excess of Th2 cytokines has also been implicated in allergic tendencies, which provides a theoretical basis for the use of quercetin as an anti-allergic substance. Conversely, animal studies have demonstrated that quercetin is able to inhibit Th1 differentiation and signalling of IL-12 (Muthian & Bright 2004) and appears to exert an effect on Th1-mediated immune responses through suppression of both IFNgamma and IL-2 cytokine production (Yu et al 2008). As a result, a possibility exists that quercetin actually exerts an immunomodulatory effect on these cells.

In mice, a short-term quercetin supplementation (12.5 mg/kg administered via gavage) for 7 days before viral challenge reduced the impact of stressful exercise on susceptibility to respiratory infection (Davis et al 2008). This effect was replicated in a human trial of 40 trained male cyclists receiving 1000 mg/day of quercetin or placebo for 2 weeks. Upper respiratory tract infection (URTI) incidence differed significantly between groups during the 2-week postexercise period (quercetin = 1/20 vs placebo = 9/20, $P = 0.004$), despite there being no significant differences in immune function tests (Nieman et al 2007).

Anti-allergy

Quercetin is structurally similar to the anti-allergic drug disodium cromoglycate (cromolyn) and has been proposed as a useful treatment for mast cell-derived allergic inflammatory diseases (Min et al 2007). Anti-asthmatic activity similar to cromolyn sodium and dexamethasone has been demonstrated in guinea pigs (Moon et al 2008).

In-vitro and animal studies demonstrate that quercetin stabilises mast cells, neutrophils and basophils inhibiting antigen as well as mitogen-induced histamine release (Blackburn et al 1987, Busse et al 1984, Middleton & Drzewiecki 1982, Middleton et al 1981, Ogasawara et al 1996, Pearce et al 1984). Inhibition of inflammatory enzymes, prostaglandins and leukotrienes, and modulation of Th2 excess may further contribute to the anti-allergic effects. Pretreatment with quercetin does not appear to produce any additional benefits.

Antihypertensive

Chronic treatment with quercetin lowers blood pressure and restores endothelial dysfunction in animal models of hypertension (Garcia-Saura et al 2005, Sanchez et al 2006). This effect may be in part due to modulation of renal function including increased urinary and sodium output (Mackraj et al 2008).

In a small randomised, double-blind, placebo-controlled, crossover study, 730 mg quercetin/day for 4 weeks resulted in reductions in mean systolic (-7 ± 2 mmHg), diastolic (-5 ± 2 mmHg) and arterial blood pressures (-5 ± 2 mmHg) ($P < 0.01$) in patients with stage 1 hypertension. Significant effects were not demonstrated in prehypertensive subjects, and indices of oxidant stress were not affected by quercetin (Edwards et al 2007).

Cardioprotective

During inflammation, circulating conjugates of quercetin pass through the endothelium to reach vascular smooth muscle cells where they exert their biological effects and are then deconjugated (Mochizuki et al 2004).

The cardioprotective effects of quercetin may be related to its vasorelaxant (Ke Chen & Pace-Asciak 1996, Roghani et al 2004), anti-inflammatory and antioxidant properties and inhibition of vascular smooth muscle cell proliferation and migration (Alcocer et al 2002, Moon et al 2003) as demonstrated in animal and in-vitro models.

Animal experiments indicate that doses of quercetin equivalent to one to two glasses of red wine exert a cardioprotective effect following ischaemia–reperfusion by improving the function of mitochondria, which play a critical role in myocardial recovery (Brookes et al 2002), and may also prevent the development of atherosclerosis through several indirect mechanisms (Auger et al 2005). Quercetin has demonstrated a protective effect against adriamycin-induced cardiotoxicity in mice. The effect is likely to be related to enhanced myocardial superoxide dismutase (SOD) activity, decreased iNOS activity and inhibition of myocardial apoptosis (Pei et al 2007). In humans, quercetin inhibits platelet

Q

aggregation and signalling and thrombus formation at a dose of 150 or 300 mg quercetin-4′-O-beta-D-glucoside (Hubbard et al 2004). This effect, however, may not occur with clinically relevant doses.

Anti-atherogenic

Adhesion of circulating monocytes to vascular endothelial cells is a critical step in both inflammation and atherosclerosis. Experimental studies have indicated that both quercetin and its metabolites can inhibit the expression of key molecules involved in monocyte recruitment during the early stages of atherosclerosis (Tribolo et al 2008), suggesting a theoretical basis for the use of quercetin in the prevention of this condition. Further human trials are required to examine this effect.

Neuroprotective

Quercetin protects neuronal cells from oxidative stress-induced neurotoxicity (Heo & Lee 2004) and inflammatory-related neuronal injury (Chen et al 2005). At lower doses, it has been proposed as a treatment for Alzheimer's disease and other oxidative stress-related neurodegenerative diseases; however, higher doses may be neurotoxic (Ansari et al 2008).

Cognitive enhancement

Anxiolytic effects have been demonstrated in stress-affected mice (Kumar & Goyal 2008) and both anxiolytic and cognitive enhancing effects in rats following quercetin treatment (Priprem et al 2008).

Gastroprotective

Quercetin treatment (100 mg/kg/day by intragastric gavage) inhibits hyperproliferation of gastric mucosal cells in rats treated with chronic oral ethanol (Liu et al 2008). It has been suggested that the gastroprotective effect of quercetin in animal models may be due to its antiperoxidative, antioxidant and antihistamine effects, resulting in a significant reduction in the number of mast cells and size of gastric erosions (Kahraman et al 2003).

Hepatoprotective

In-vitro and animal studies have demonstrated the hepatoprotective effects of quercetin. It protects the liver from oxidative damage and may reduce biliary obstruction (Alia et al 2006, Peres et al 2000). In experimental models, quercetin protects human hepatocytes from ethanol-induced oxidative stress (Yao et al 2007) and reduces liver fibrosis in rats by enhancing antioxidant enzyme activity (Amalia et al 2007). Pretreatment of rats with quercetin (10 mg/kg) reduced the mortality rate for paracetamol (1 g/kg) from 100 to 30% and prevented liver damage at sublethal doses (640 mg/kg) (Janbaz et al 2004).

Chemoprotective

In the 1970s, quercetin was considered to be carcinogenic after demonstrating mutagenicity in the Ames test; however, subsequent long-term studies have refuted this and demonstrated an anticarcinogenic effect in laboratory animals (Erlund 2004). Epidemiological and experimental studies have demonstrated potential benefits for melanoma (Thangasamy et al 2007), colon, lung (Murakami et al 2008), breast (Lin et al 2008) and liver cancer (Mu et al 2007). Further research is warranted.

In-vitro and preliminary animal and human data indicate that quercetin inhibits tumour growth and induces apoptosis. The anticarcinogenic effects may be due to its antioxidant properties, protection against DNA damage, inhibition of angiogenesis, effects on gene expression, effects on cell cycle regulation, phyto-oestrogen-like activity, interaction with type II oestrogen binding sites and tyrosine kinase inhibition (Zhang et al 2008, Duraj et al 2005, Erlund 2004, Igura et al 2001, Lamson & Brignall 2000, Lee et al 2003, 2005, Tan et al 2003, van der Woude et al 2005, Wilms et al 2005). Quercetin may also protect against nicotine-induced cellular and DNA damage in rats by modulating lipid peroxidation and augmenting antioxidant defence systems (Muthukumaran et al 2008a, 2008b). Radioprotective effects have also been reported (Devipriya et al 2008).

Antidiabetic effects

Oral administration of quercetin (10 mg/kg body weight) to diabetic rats restores vascular function, and this is thought to be due to enhancement in the bioavailability of endothelium-derived nitric oxide as well as a reduction in blood glucose levels and oxidative stress (Machha et al 2007). Diabetic rats receiving quercetin (15 mg/kg/day) for 4 weeks also experienced a decrease in blood glucose and an increase in plasma insulin, calcium and magnesium (Kanter et al 2007). In addition, quercetin has been shown to inhibit human lens aldose reductase by 50% in vitro (Chaudhry et al 1983) and may be responsible for the reduction in cataract formation observed in diabetic rats receiving either dietary or topical quercetin (Beyer-Mears & Farnsworth 1979).

Preventing bone loss

In rabbits, the addition of quercetin to a collagen matrix has been shown to increase new bone formation (Wong & Rabie 2008). Quercetin is claimed to play an important role in preventing bone loss by affecting osteoclastogenesis and regulating many systemic and local factors, including hormones and cytokines (Son et al 2006), providing a theoretical basis for its use in the prevention of postmenopausal bone loss. In-vitro studies demonstrate that bone resorption is mediated by oestrogen receptor proteins through the inhibition of receptor activator of nuclear factor kappa beta (RANK) protein or the activation of caspases (Rassi et al 2005, Wattel et al 2003). However, in-vitro studies also suggest that quercetin inhibits the metabolism of not only osteoclasts (bone resorption cells) but also osteoblasts (bone-forming cells), and therefore, further research is required to elucidate whether quercetin increases or decreases bone mass in vivo (Notoya et al 2004).

Sperm quality

High doses of quercetin delivered by injection to rats resulted in improved sperm motility, viability and concentration and increased the weight of the

testes, epididymis and vas deferens (Taepongsorat et al 2008). Oral administration of quercetin and onions (containing quercetin) to mice has also been shown to reduce the male reproductive toxicity (sperm abnormalities) induced by diesel exhaust particles (Izawa et al 2008). The potential significance of these results to humans is unclear.

OTHER ACTIONS

Quercetin has been shown to reduce oxalate-induced urinary crystal formation and increase catalase and SOD activities in rats (Park et al 2008).

CLINICAL USE

Allergies

Quercetin is used in the treatment of acute and chronic allergic symptoms, such as hayfever and chronic rhinitis. The anti-inflammatory activity of quercetin and its ability to block substances involved in allergies provide a rationale for its use in these indications. Quercetin stabilises mast cells, neutrophils and basophils and inhibits histamine release (Blackburn et al 1987, Busse et al 1984, Middleton & Drzewiecki 1982, Middleton et al 1981, Ogasawara et al 1996, Pearce et al 1984). It acts as an inhibitor of mast cell secretion; reduces the release of tryptase, monocyte chemotactic protein-1 (MCP-1) and IL-6 and down-regulates histidine decarboxylase mRNA from several mast cell lines (Shaik et al 2006).

In a study of 123 patients sensitised to house dust mite and displaying nasal symptoms of mild to severe perennial allergic rhinitis (Otsuka et al 1995), nasal scrapings were taken and histamine release measured as a percentage of the total content in the specimen. Antigen exposure resulted in an increase in mast cells of the epithelial layer of the nasal mucosa, resulting in nasal hypersensitivity. Quercetin inhibited histamine release by 46–96% in a dose-dependent manner.

Large-scale human trials are required to fully elucidate the potential for quercetin to inhibit allergic symptoms caused by the release of histamine.

Asthma

Quercetin has also been used as an adjunct in the management of asthma, often in combination with vitamin C because of its anti-allergic activity and ability to inhibit leukotriene synthesis (Formica & Regelson 1995). Controlled studies are still required to determine its effectiveness.

Preventing diabetic complications

As quercetin has been shown to inhibit aldose reductase, the first enzyme in the polyol pathway, a theoretical basis exists for its use in the prevention of long-term diabetic complications such as cataracts, nephropathy, retinopathy and neuropathy (Chaudhry et al 1983). Quercetin may also provide beneficial effects in people with diabetes by decreasing oxidative stress and preserving pancreatic beta-cell integrity (Coskun et al 2005).

Preliminary evidence suggests a possible antinociceptive activity of quercetin, probably through modulation of opioidergic mechanism, suggesting a potential for the treatment of diabetic neuropathic pain (Anjaneyulu & Chopra 2003). Topical application of quercetin in combination with ascorbyl palmitate and vitamin D3 has been tested in a randomised, placebo-controlled, double-blind trial of 34 men and women (age 21–71 years) with diabetic neuropathy. The QR-333 preparation or placebo was applied three times daily for 4 weeks to each foot experiencing symptoms. QR-333 was well tolerated and reduced the severity of numbness, jolting pain and irritation from baseline values and improved quality of life (QOL) scores (Valensi et al 2005).

The diabetic status of rats fed high-dose quercetin (1 g/kg) was found to be ameliorated by approximately 25%; however, the amounts used were considerably higher than those commonly used in humans (Shetty et al 2004). Intraperitoneal injection of quercetin has also demonstrated an ability to improve glucose tolerance and cholesterol and triglyceride levels in diabetic, but not normoglycaemic, rats and increase the number of pancreatic islets in both groups (Vessal et al 2003). However, these results cannot necessarily be applied to oral doses in humans, and further research is required to confirm any potential benefits.

Cataracts

In addition to the potential reduction in diabetic cataract formation afforded by the inhibition of aldose reductase (Ramana et al 2007, Chaudhry et al 1983), quercetin may also reduce oxidative stress associated with the initiation of maturity-onset cataracts.

Cataracts may result from oxidative damage to the lens, which causes a disruption of the redox system, membrane damage, proteolysis, protein aggregation and a loss of lens transparency. Quercetin has been shown to inhibit oxidative damage to the lens and maintain lens transparency in vitro (Cornish et al 2002, Sanderson et al 1999). In rats with galactosaemic cataracts, quercetin improves lens transparency by maintaining the characteristic osmotic ion (calcium, sodium and potassium) equilibrium and protein levels of the lens (Ramana et al 2007). Further trials are warranted to confirm the effects of oral doses in humans.

Preventing cardiovascular disease

The cardioprotective properties of quercetin, demonstrated in animal and in-vitro studies, provide a theoretical basis for the use of quercetin in the prevention of cardiovascular disease; however, current human data are less encouraging.

A double-blind placebo-controlled study investigating the effects of a quercetin-containing supplement on plasma quercetin status, risk factors for heart disease and serum/platelet fatty acid levels was conducted on 27 healthy men and women with cholesterol levels of 4.0–7.2 mmol/L (Conquer et al 1998). The subjects consumed a quercetin-containing supplement (1 g quercetin/day) or rice flour placebo for 28 days. Quercetin intakes were approximately 50-fold greater than dietary intakes previously associated with lower coronary heart

disease mortality in epidemiological studies. Plasma quercetin concentrations were approximately 23-fold greater in subjects consuming the quercetin capsules than in the placebo group. Quercetin supplementation did not alter serum total, LDL or high density lipoprotein (HDL) cholesterol or triglyceride levels or other cardiovascular disease or thrombogenic risk factors such as platelet thromboxane B2 production, blood pressure or resting heart rate. This is in contrast to a previous trial (Hubbard et al 2004), which demonstrated inhibition of platelet aggregation and signalling and thrombus formation at a dose of 150 or 300 mg quercetin-4′-O-beta-D-glucoside. There was also no effect on the levels of omega-3 or omega-6 polyunsaturated fatty acids in serum or platelet phospholipids (Conquer et al 1998). Further investigation with larger and long-term trials is required to determine the effects and safety of quercetin in the prevention of cardiovascular disease in humans.

Metabolic syndrome

In obese rats, quercetin treatment (2 or 10 mg/kg of body weight for 10 weeks) resulted in a reduction in elevated systolic blood pressure, triglycerides, total cholesterol, free fatty acids and insulin. The higher dose also produced anti-inflammatory effects (Rivera et al 2008).

Chronic prostatitis

Thirty men with category IIIa or IIIb chronic pelvic pain syndrome received either placebo or quercetin 500 mg twice daily for 1 month. Sixty-seven per cent of the treated subjects had at least a 25% improvement in symptoms compared to 20% of the placebo group. In a follow-up, unblinded, open-label study, 17 additional men received the same dose of quercetin (combined with bromelain and papain to enhance absorption) for 1 month. The combination increased the response rate from 67 to 82% (Shoskes et al 1999). The anti-inflammatory, antioxidant and immunomodulating activities of quercetin may help to explain these results.

Cancer

Early concerns that quercetin may be carcinogenic have not been supported by recent research. Quercetin is primarily found in fruit and vegetables, which have been shown to decrease the risk of certain human cancers when consumed regularly (Morrow et al 2001), thereby casting doubt on this proposition. In fact, the anticarcinogenic effects of quercetin seen in laboratory animals suggest a possible preventative role (Erlund 2004), and in-vitro and epidemiological studies have suggested potential benefits in the prevention of colon (Kim et al 2005, Park et al 2005), lung (Schwarz et al 2005), prostate (Yuan et al 2004) and breast cancer (Otake et al 2000).

Human studies using extremely low-dose supplementation of quercetin (30 mg/day) have so far provided more questions than answers about the exact mechanism(s) by which quercetin may exert its effects but much remains unknown (Morrow et al 2001).

OTHER USES

Although the potential benefits of quercetin in allergic conditions have yet to be elucidated by human trials, quercetin is often used to treat conditions such as hayfever and other respiratory allergies and histamine-related conditions. In practice, quercetin is also commonly used to stabilise the integrity of blood vessel walls and address conditions resulting from capillary fragility and used in conjunction with vitamin C for the treatment of viral infections.

DOSAGE RANGE

General dose range

- 200–1500 mg daily taken in divided doses (PDR-Health 2005, Spoerke & Rouse 2004)

Specific doses

- Chronic prostatitis: 500 mg (combined with bromelain and papain to enhance absorption) twice daily (Shoskes et al 1999)
- Acute allergies: 2 g every 2 h for 2 days (often used with vitamin C)
- Chronic allergies: 2 g daily
- Asthma: as an adjunct to standard treatment 2 g daily

ADVERSE REACTIONS

Quercetin is generally well tolerated and appears to be associated with little toxicity when administered orally or intravenously (Lamson & Brignall 2000). Adverse effects may include nausea, dyspnoea, headache and mild tingling of the extremities (PDRHealth 2005, Spoerke & Rouse 2004).

SIGNIFICANT INTERACTIONS

Possible modulation of P-glycoprotein (Choi & Li 2005, Hsiu et al 2002, Limtrakul et al 2005) and inhibition of CYP1A1 (Schwarz et al 2005), CYP1A2 (Chang et al 2005) and CYP 3A4 (Choi & Li 2005) activity should be considered when prescribing.

Note: Phase II metabolites of quercetin appear to inhibit human multidrug resistance-associated protein 1 (MRP1) and 2 (MRP2), which may prove beneficial in MRP-mediated multidrug resistance (van Zanden et al 2007). For instance, the combined effect of quercetin with hyperthermia in human myelogenous leukaemia cells may assist in the reversal of multidrug resistance (Shen et al 2008).

Adriamycin

Quercetin has demonstrated a protective effect against adriamycin-induced cardiotoxicity in mice. The effect is likely to be related to enhanced myocardial SOD activity, decreased iNOS activity and inhibition of myocardial apoptosis (Pei et al 2007).

Cisplatin

Quercetin pretreatment may sensitise human cervix carcinoma cells to cisplatin-induced apoptosis (Jakubowicz-Gil et al 2005). Beneficial interaction is theoretically possible under professional supervision, but clinical significance is unknown.

Cyclosporin
Animal studies demonstrate that co-administration of quercetin significantly decreases the oral bioavailability of cyclosporin (Hsiu et al 2002) — avoid concurrent use.

Digoxin
An increase in drug bioavailability is theoretically possible and has been observed in an in-vivo study. Although human studies at lower doses are not available, the narrow therapeutic range of digoxin and the serious nature of the interaction should not be underestimated. Avoid concurrent use.

Diltiazem
Pretreatment of rabbits with quercetin resulted in an increased bioavailability of the calcium channel blocker, diltiazem, which may be the result of inhibition of P-glycoprotein and CYP 3A4 (Choi & Li 2005). Caution — use under professional supervision; doses may need to be adjusted accordingly.

Doxorubicin
Quercetin appears to significantly inhibit the formation of cardiotoxic doxorubicinol without affecting the transport of [14C]doxorubicin in human resistant breast cancer cells. It may therefore be useful in reducing doxorubicin-mediated toxicity (Vaclavikova et al 2008) under professional supervision.

Haloperidol
Tardive dyskinesia (rhythmical involuntary movements of the tongue, face, mouth or jaw, e.g. protrusion of tongue, puffing of cheeks, puckering of mouth and chewing movements) may result from long-term therapy with the antipsychotic medication haloperidol and may be irreversible in some individuals with no known effective treatment. Oxidative stress and the products of lipid peroxidation have been implicated in the pathophysiology of tardive dyskinesia, and co-administration of quercetin (25–100 mg/kg) has been shown to dose dependently reduce haloperidol-induced vacuous chewing movements and tongue protrusions in animal models (Naidu et al 2003). Beneficial interaction is theoretically possible under professional supervision.

Paclitaxel
Pretreatment with quercetin may increase the bioavailability of paclitaxel according to animal studies (Choi et al 2004). Caution — use under professional supervision; doses may need to be adjusted accordingly.

Paracetamol
According to animal data, pretreatment with quercetin may reduce the risk of mortality from paracetamol overdose (Janbaz et al 2004). However, effects in humans have not been studied — beneficial interaction theoretically possible.

Pioglitazone
Quercetin may increase the bioavailability of pioglitazone (Actos) (Umathe et al 2008). Due to the potential for toxicity, careful monitoring of hepatic and cardiac function is required — Caution.

Quinolone antibiotics
In vitro, quercetin binds to the DNA gyrase site in bacteria and therefore may theoretically compete with quinolone antibiotics that also bind to this site (PDRHealth 2005) — caution.

Saquinavir
Despite the inhibition of P-glycoprotein by quercetin, co-administration does not appear to alter plasma saquinavir concentrations. However, as there appears to be a substantial inter- and intra-subject variability in saquinavir intracellular concentrations, caution should be exerted until more is known (DiCenzo et al 2006).

Stibanate
Concurrent use of quercetin with the antileishmanial drug stibanate appears to improve the efficacy of the drug and reduce anaemia and parasitaemia associated with the condition (Sen et al 2005) — beneficial interaction theoretically possible.

CONTRAINDICATIONS AND PRECAUTIONS
Hypersensitivity to quercetin.

According to experimental studies, quercetin may possess some antithyroid properties, inhibiting thyroid cell growth in association with inhibition of insulin-modulated phosphatidylinositol 3-kinase-Akt kinase activity. While these findings are preliminary, quercetin should be used with caution in thyroid disease and therapy until more is understood about these effects in humans (Giuliani et al 2008).

PREGNANCY USE
Safety in pregnancy has not been established.

PRACTICE POINTS/PATIENT COUNSELLING
- Quercetin is a flavonol belonging to a group of polyphenolic substances known as flavonoids or bioflavonoids and is found in many fruits, vegetables and some herbal medicines.
- According to experimental studies, it has antioxidant, anti-inflammatory, antiviral, mast cell stabilisation, neuroprotective, gastroprotective, hepatoprotective and possibly cardioprotective actions.
- In practice, it is used for respiratory allergies such as hayfever, as an adjunct in asthma management, preventing diabetic complications such as cataracts and symptom relief in prostatitis; however, large controlled studies are not available to determine its effectiveness.
- Numerous drug interactions are theoretically possible, mainly due to P-glycoprotein and CYP inhibition.
- Quercetin is generally well tolerated. Adverse effects may include nausea, dyspnoea, headache and mild tingling of the extremities.

PATIENTS' FAQS

What will this supplement do for me?

Quercetin has several pharmacological effects and may provide some symptom relief in allergic conditions and prostatitis and may be beneficial in diabetes and cardiovascular disease; however, further research is required to clarify its effectiveness.

When will it start to work?

This will depend on the indication it is being used to treat.

Are there any safety issues?

Although it is generally well tolerated, numerous drug interactions are possible, so seek professional advice if taking other medication.

Raspberry leaf

HISTORICAL NOTE Although the fruits of the raspberry are used as a luxury food source and in dietary drinks, midwives have used raspberry leaves since ancient times to prepare the uterus for childbirth. Raspberry has also been used as an antidiarrhoeal agent and an astringent to treat inflammations of the mucous membranes of the mouth and throat.

COMMON NAME
Red raspberry

OTHER NAMES
Framboise, *Rubi idaei folium*, rubus

BOTANICAL NAME/FAMILY
Rubus idaeus (synonym: *Rubus strigosus*) (family Rosaceae [roses])

PLANT PART USED
Leaf

CHEMICAL COMPONENTS
Raspberry leaves have a tannin content of between 13% and 15%, as well as phenolic compounds like the flavonoids rutin and quercetin, volatile oils, organic acids and vitamin C.

MAIN ACTIONS
Raspberry leaf contains a number of active constituents and their therapeutic actions have been reviewed (Patel et al 2004). Currently, evidence of activity comes from in vitro and in vivo studies.

Uterine effects
Raspberry leaf has demonstrated a variable effect on uterine muscle tone as it contains a smooth muscle stimulant, an anticholinesterase and an antispasmodic. The results of animal studies indicate that raspberry can either reduce or initiate uterine contractions (Bamford et al 1970). It appears to inhibit uterine contractions in samples from pregnant test animals, but has no effect in non-pregnant ones. Samples from human pregnant uteri respond with contraction effects; however, no effect was seen on non-pregnant uteri samples. Overall, it appeared that raspberry leaf extract promoted more regular contractions that generally became less frequent (Newell et al 1996). A more recent preliminary study produced similar results with fractions of raspberry leaf extract, both stimulating and relaxing uterine muscle in pregnant rats (Briggs & Briggs 1997). There is evidence of at least two components of raspberry leaf extract that exhibit relaxant activity in an in vitro guinea pig ileum preparation (Rojas-Vera et al 2002). Results imply a regulatory action on contractions.

Antidiarrhoeal
In addition to the high tannin content of the leaves which may exert an antidiarrhoeal action, raspberry cordial and juice, made from the fruits, were found to significantly reduce the growth of several species of gut bacteria, including *Salmonella*, *Shigella* and *Escherichia coli*. However, no antimicrobial activity was detected in the leaf extract or tea (Ryan et al 2001).

Anti-inflammatory
Raspberry leaf exhibits anti-inflammatory activity because of its high tannin content, which has been found to inhibit COX (Duke 2003). When applied topically to mucous membranes, tannins have a local anti-inflammatory effect, produce capillary vasoconstriction and decrease vascular permeability (Halvorsen et al 2001).

Astringent
The high tannin content of the leaf is responsible for the astringent activity.

OTHER ACTIONS
The phenolic content of raspberry leaves may provide antioxidant protection against oxidative stress that can induce neuronal damage. Raspberry ketone, which is an aromatic compound with similar structure to capsaicin and synephrine, has been shown in vivo to prevent and improve obesity and fatty liver though increasing noradrenaline-induced lipolysis in white adipocytes (Morimoto et al 2005).

CLINICAL USE
The therapeutic effects of raspberry have not been significantly investigated under clinical trial conditions, so most evidence is derived from traditional, in vitro and animal studies.

Uterine tonic
Raspberry leaf is commonly used as a 'partus preparator' to prepare the uterus for delivery and to facilitate labour, as well as for treating morning sickness, dysmenorrhoea, leucorrhoea and menorrhagia (McFarlin et al 1999). A study of 588 pregnant women of 36–38 weeks' gestation who were attending a public tertiary maternity hospital in Melbourne, Australia were surveyed to measure the prevalence of herbal medicine use in pregnancy. Thirty-six percent of women took at least one herbal supplement during the current pregnancy, their most common supplement being raspberry leaf (14%).

In vitro studies using pregnant rat and human uteri preparations suggest that raspberry may increase the regularity and decrease the frequency of uterine contractions (Bamford et al 1970). In a double-blind trial of 192 low-risk nulliparous women, raspberry leaf (2 × 1.2 g/day), consumed from 32 weeks' gestation until labour, was associated with a lower rate of interventions with no adverse effects for mother or baby (Simpson et al 2001). Raspberry leaf did not shorten the first stage of labour; however, it did significantly reduce the second stage. A retrospective, observational study of 108 mothers also found that treatment with raspberry leaf was associated with a lower rate of medical intervention (Parsons et al 1999). This study further suggested that treatment may shorten labour, and reduce the incidence of pre- and post-term labour. Some pregnant women commenced use of raspberry leaf from 8 weeks' gestation; however, most chose to start it between 30 and 34 weeks' gestation.

Topical inflammatory conditions
The high tannin content of raspberry supports its traditional use as a topical treatment for inflammation of the mouth, throat, eye and skin, as well as to treat cuts and wounds.

Diarrhoea
Once again, the high tannin content of raspberry supports its traditional use as an antidiarrhoeal agent.

Dyspeptic complaints
Traditionally understood to act as a choleretic, raspberry leaf is used to improve digestion and detoxifying processes, but controlled studies are not available to determine its effectiveness.

OTHER USES
Raspberry leaf is commonly recommended for nausea and vomiting in pregnancy, but this advice is based more on anecdotal evidence than rigorous scientific evidence, highlighting a need for more research in this area.

Cold infusions of raspberry leaf have been used to treat diarrhoea, loose bowels and stomach complaints in children. Raspberry leaf has traditionally been incorporated into mouthwashes to treat inflammation of the mouth and throat, used as a diaphoretic for fever, as a choleretic to improve digestion and detoxification, and as a food and flavouring agent.

In a small, uncontrolled, prospective pilot study of eight women, raspberry leaf in combination with

11 other botanical extracts was found to relieve menopausal symptoms (Smolinski et al 2005).

DOSAGE RANGE

Internal use

- Infusion of dried leaf: 4–8 g taken up to three times daily.
- Liquid extract: (1:1): 4–8 mL three times daily.

External use

- Topically, the tea can be used as a mouth or eye wash, or to clean wounds.

TOXICITY

There is no evidence that raspberry leaf tea is toxic.

ADVERSE REACTIONS

Owing to the tannin content of the herb, it may cause gastrointestinal discomfort.

SIGNIFICANT INTERACTIONS

Iron, calcium, magnesium

Due to its high tannin content, raspberry leaf may decrease absorption of iron, calcium and magnesium, as well as some drugs. As such, it is advised to separate the administration of these substances by at least 2 h.

CONTRAINDICATIONS AND PRECAUTIONS

The high tannin concentration within the herb means it should be avoided in constipation and used cautiously in active peptic ulcer and gastrointestinal conditions associated with inflammation.

PREGNANCY USE

There is no evidence of harmful effects on the fetus, despite consumption by a large number of women. Clinical studies suggest that it is safe to use after the first trimester, although it is prudent to ensure close professional supervision.

PATIENTS' FAQs

What will this herb do for me?

Raspberry leaf preparations have been used since ancient times to prepare the uterus for birth in an attempt to facilitate a complication-free labour. It is also used to treat diarrhoea and dyspeptic complaints, and incorporated into a mouthwash to reduce inflammation of the mouth and throat.

When will it start to work?

Currently, there is insufficient research to answer this question. However, it is used in increasing doses during the last few weeks of pregnancy. Symptomatic relief of diarrhoea and inflammation of the oral cavity is likely to occur within the first few doses.

Are there any safety issues?

Considering that raspberry leaf has uterine activity, it is recommended that pregnant women wanting to use it do so under the careful supervision of an experienced healthcare professional.

PRACTICE POINTS/PATIENT COUNSELLING

- Raspberry leaves have been traditionally used to prepare the uterus for childbirth, with some modern research suggesting that they may be useful.
- When used in this way, raspberry leaf is often combined with other herbs and used during the last 6–8 weeks of pregnancy under close supervision.
- Raspberry leaves are high in tannins, which may make them useful as a mouthwash and to treat diarrhoea, although this has not been confirmed in clinical trials.
- As tannins may reduce the absorption of other substances, it is recommended to take raspberry leaf preparations separately from other medications. Raspberry leaf preparations can be considered safe and non-toxic.

Red clover

HISTORICAL NOTE Red clover has been used for a long time as an animal fodder as well as a human medicine. Traditionally, it is considered as an alterative remedy with blood cleansing properties useful in the treatment of skin diseases such as psoriasis, eczema and rashes. A strong infusion was used to ease whooping cough and other spasmodic coughs due to measles, bronchitis and laryngitis. It was recommended for 'ulcers of every kind, and deep, ragged-edged, and otherwise badly-conditioned burns. It possesses a peculiar soothing property, proves an efficient detergent, and promotes a healthful granulation'. Combined with other herbs, red clover was recommended for syphilis, scrofula, chronic rheumatism, glandular and various skin affections (Felter & Lloyd 1983). Interestingly, red clover was not traditionally used for the treatment of menopausal symptoms.

OTHER NAMES

Cow clover, meadow clover, purple clover, trefoil

BOTANICAL NAME/FAMILY

Trifolium pratense L. (family Fabaceae)

PLANT PARTS USED

Flower head or leaf

CHEMICAL COMPONENTS

Flower head

Flavonoids, including formononetin; flavonols, including isorhamnetin and quercetin glucosides; phenolic acids, including salicylic and p-coumaric acids; volatile oils and other constituents, including sitosterol, starch, fatty acids (British Herbal Medicine Association Scientific Committee 1983).

Leaf

Isoflavones, including biochanin A, daidzein, formononetin and genistein; caffeic acid derivatives; and coumestrol (trace) (Clifton-Bligh et al 2001, He et al 1996).

In the plant, the isoflavones are attached to a sugar molecule, usually glucose. The chemical term for any compound attached to a sugar is 'glycoside'. The free isoflavone form is known as an 'aglycone'. The active aglycone is liberated in the gut. Isoflavones are readily absorbed from the gut; they circulate freely in the blood and are excreted in the urine; 50% of ingested isoflavones are eliminated within 12 h (Joannou et al 1995).

The aglycone forms of the four main oestrogenic isoflavones are genistein, daidzein, biochanin and formononetin.

MAIN ACTIONS

Oestrogenic activity

The pharmacological investigation of red clover has mainly centred around the activity of the isoflavone constituents, especially their oestrogenic activity (Miksicek 1994). Red clover products contain primarily formononetin and biochanin A. The isoflavones have varying levels of subtle oestrogenic activity, biochanin A having the strongest effect. Red clover isoflavones have been shown to have an affinity for oestrogen alpha- and beta-receptors and may act as both agonists and antagonists, depending on the level of endogenous oestrogens (Nelson et al 2006, Zava et al 1998). The isoflavones in red clover (and soy extracts) act as selective oestrogen receptor modulators (SERMs) as well as selective oestrogen enzyme modulators (SEEMs). The higher affinity of isoflavones to oestrogen beta-receptors compared to oestrogen alpha-receptors has been used to explain why red clover extracts treat menopausal disorders, reduce risk of breast cancer and have protective effects on osteoporosis and the cardiovascular system (Beck

Clinical note — Phyto-oestrogens and isoflavones

Phyto-oestrogens are plant-based compounds that are structurally similar to oestradiol. The term phyto-oestrogen encompasses isoflavone compounds, such as genistein and daidzein, found predominantly in soy and red clover, and the lignans, such as matairesinol and secoisolariciresinol, found in many fruits, cereals and in linseed. Phyto-oestrogens have been investigated for their potential to reduce the risk of hormone-dependent diseases such as breast and prostate cancers and osteoporosis. The metabolism of isoflavones and lignans is complex and involves gut microbial processes. Isoflavones are present predominantly as glucosides; however, their bioavailability requires initial hydrolysis of the sugar moiety by intestinal beta-glucosidases. After absorption, phyto-oestrogens are reconjugated predominantly to glucuronic acid and to a lesser degree to sulfuric acid. There is further metabolism of isoflavones (to equol and O-desmethyl-angolensin) and lignans (to enterodiol and enterolactone) by gut bacteria. In humans, even those on controlled diets, there is large inter-individual variation in the metabolism of isoflavones and lignans, particularly in the production of the gut bacterial metabolite equol (from daidzein). Dietary factors and gut microflora directly influence the absorption and metabolism of phyto-oestrogens and is likely to influence the clinical benefits of supplementation with phyto-oestrogens (Rowland et al 2003).

et al 2005). Animal studies show that red clover extract, standardised to contain 15% isoflavones, produced a dose-dependent increase in uterine weight and differentiated vaginal cells, but did not stimulate cell proliferation in mammary glands in an ovariectomised rat model. The extract did not produce any anti-oestrogenic or additive oestrogenic effects when combined with 17-beta-oestradiol (Burdette et al 2002). Supplementing isoflavones, either daidzein (at 100 mg/kg) or red clover extract (at 6.68 mg/kg), in menopausal rabbits also showed significant improvements in bone density, tissue integrity and vaginal blood flow with minimal effect on uterine weight (Adaikan et al 2008).

Antioxidant activity

The isoflavones in red clover display antioxidant activity at concentrations well within the range found in the plasma of subjects consuming soy products even though they undergo extensive metabolism in the intestine and the liver (Rufer & Kulling 2006).

Opioid activity

A new understanding of a potential mechanism of action for red clover has been identified which involves interaction with opiate receptors. Red clover extract has high binding affinity for the mu-opiate receptor and also affinity at the delta-opiate receptor. Given the essential role of the opioid system in regulating temperature, mood and hormonal levels this newly identified activity provides further rationale for its investigation as a treatment for relieving menopausal symptoms (Nissan et al 2007).

Reducing cancer risk

Phyto-oestrogens and isoflavones may reduce the risk of cancer, including breast cancer; however, the evidence is still not definitive (Adlercreutz et al 1995, Clarke et al 1996, Ingram et al 1997, Pagliaaci et al 1994). Biochanin A isolated from red clover has been shown to be antimutagenic, as well as protective against chemically induced DNA damage in vitro (Chan et al 2003). Genistein has been shown to inhibit cell proliferation and in vitro angiogenesis (Fotsis et al 1995).

An animal study has found that red clover isoflavones significantly increase oestrogen beta-receptor and E-cadherin expression, but decrease transforming growth factor beta-1. These proteins are markers of oestrogen-induced proliferation, preservation of cell phenotype and reduction of the potential for neoplastic and metastatic transformation. These results suggest that red clover isoflavones may be useful in the treatment of prostatic hyperplasia and reduce the risk of neoplastic transformation (Slater et al 2002). A study has reported that red clover-derived isoflavones significantly reduced non-malignant prostatic growth in mice by acting as antiandrogenic agents rather than weak oestrogenic substances (Jarred et al 2003). The metabolites of the red clover isoflavone, biochanin, are thought to contribute to its chemopreventive effects.

Biochanin A, daidzein and genistein have demonstrated antiproliferative activity in vitro (Hempstock et al 1998). In a recent in vitro study, red clover isoflavones were tested for their potential in transactivating aryl hydrocarbon receptor (AhR), which is known to affect the cell cycle and drive cells to apoptosis. Selective AhR modulators (SAhRMs) have previously been implicated in cancer therapy and prevention, particularly for hormone-dependent cancers. It was found that the isoflavones biochanin A and formononetin were potent AhR agonists in vitro, 10 times more potent compared to the indole compounds (Medjakovic & Jungbauer 2008). Red clover isoflavones (50 mg total isoflavones), however, were found not to be antiproliferative in a double-blind, randomised study of 30 perimenopausal women (Hale et al 2001).

CLINICAL USE

Considerable research has been carried out on the constituents of red clover; however, very few investigations have concentrated specifically on the flower heads and the traditional uses.

Relief of menopausal symptoms

Numerous clinical studies have been conducted using red clover extracts or isoflavones, which are found in red clover in varying concentrations. Many isoflavone studies do not report whether these constituents were derived from red clover or other sources making interpretation of the data difficult.

Red clover extract studies

The general consensus from systematic reviews and meta-analyses is that there is a lack of evidence to support the use of monopreparations containing *Trifolium pratense* isoflavones as a means of significantly reducing hot flush frequency, severity or other menopausal symptoms (Booth et al 2006, Cheema et al 2007, Coon et al 2007, Lethaby et al 2007, Low Dog 2005, Nelson et al 2006).

The most recent meta-analysis evaluated data from five randomised clinical trials of monopreparations containing *Trifolium pratense* isoflavones (40–82 mg daily) and concluded that active treatment resulted in a marginally significant effect reducing frequency of hot flushes in menopausal women, although the size of this effect may not be considered clinically relevant (Coon et al 2007). In 2007, Lethaby et al also reported in their systematic review that of the five trials with data suitable for pooling that assessed daily frequency of hot flushes, there was no significant difference overall in the frequency of hot flushes between Promensil (a red clover extract) and placebo. Furthermore, a systematic review by Low Dog et al (2005) stated the largest study showed minimal to no effect in reducing menopausal symptoms.

Isoflavone studies

Several reviews have evaluated the clinical evidence relating to isoflavone treatment in the relief of menopausal hot flushes finding conflicting and ambiguous results. Some of this confusion may arise from the fact that a variety of isoflavone sources

have been tested, often without discriminating between the identities of individual isoflavones or the different concentrations contained in the tested intervention product. As such, volunteers may be receiving greatly different doses or ranges of specific isoflavones from the different test products, but researchers have not taken this into account when evaluating and comparing results.

A review by Williamson and Hughes highlights this issue and the importance of clearly defining the chemical composition of isoflavone treatments in research reports. The authors evaluated results from 11 studies that tested similar total isoflavone doses (Williamson-Hughes et al 2006). Five of the eleven studies (n = 177) reported a statistically significant decrease in hot flush symptoms. Later evaluation revealed that the test products used in these studies provided more than 15 mg genistein (calculated as aglycone equivalents) per treatment. Of the remaining six studies (n = 201), five failed to find a significant decrease in hot flush symptoms. Participants in these studies received less than 15 mg genistein per treatment. Thus, the reduction in hot flushes was related to genistein content and not total isoflavone content of the treatments.

Interestingly, a 12-month, prospective, randomised, double-blind, placebo-controlled study demonstrated that the phytoestrogen genistein (54 mg/day) from red clover reduced the number and severity of hot flushes in postmenopausal women with no adverse effect on the endometrium (D'Anna et al 2007).

In combination

A nutritional supplement containing isoflavones from kudzu and red clover, along with other targeted nutrients, produced a 46% decrease in hot flush frequency, and quality of life, as assessed by the standardised Greene Questionnaire, showed similar improvement in a small pilot study of 25 menopausal women suffering from severe hot flushes and night sweats (Lukaczer et al 2005). A modest improvement in the ratio of total cholesterol to high-density lipoprotein (HDL) cholesterol was also observed and a statistical improvement in a proposed marker of breast cancer risk (the ratio of 2-hydroxyestrone to 16 alpha-hydroxyestrone) was also demonstrated. Whilst promising, the role of red clover in achieving these results remains unknown.

Other potential benefits in menopause

A randomised controlled trial using a standardised extract of red clover found that red clover exerts a moderate effect on testosterone levels in postmenopausal women, while oestradiol levels remained unchanged (Imhof et al 2006). The significance of this finding for clinical practice remains unknown.

Cardiovascular effects

Lipid lowering

A 2006 systematic review of randomised controlled trials, which included peri- or postmenopausal women, concluded that red clover extracts reduce levels of triglycerides and increase high-density lipoprotein cholesterol (Geller & Studee 2006). Given the lack of serious safety concerns in the short term, it would appear that including red clover in the diet of postmenopausal women might be beneficial. There is little convincing evidence that red clover extract significantly reduces total cholesterol or LDL cholesterol levels.

A randomised, placebo-controlled, crossover study of 60 postmenopausal women found that red clover isoflavones (80 mg/day) significantly decreased total cholesterol, LDL cholesterol and lipoprotein A levels in women with BMI > 25 kg/m^2 but not women with lower BMI (Chedraui et al 2008).

Blood pressure

Clinical studies have not consistently shown red clover isoflavones to significantly reduce blood pressure (Atkinson et al 2004b, Teede et al 2003); however, there is evidence that red clover isoflavones reduce arterial stiffness and total vascular resistance (Fugh-Berman & Kronenberg 2001, Nestel et al 1999, Teede et al 2003). A reduction in blood pressure and improved endothelial function was reported for red clover isoflavones (approximately 50 mg/day) in a small randomised, double-blind, crossover trial (n = 16) involving postmenopausal women with type 2 diabetes (Howes et al 2003).

Given the lack of serious safety concerns, red clover supplementation might be beneficial for postmenopausal women to reduce cardiovascular risk.

Reducing cancer risk

Much of the research in this area has focussed on isoflavones generally derived from soy products rather than red clover sources. As such, it is uncertain whether the results from these studies can be extrapolated to red clover extracts. For more information about the association between soy isoflavones and cancer risk, refer to the soy monograph.

Prostate cancer

A non-randomised, non-blinded trial of 38 men with clinically significant prostate cancer found that 160 mg/day red clover-derived dietary isoflavones, containing a mixture of genistein, daidzein, formononetin and biochanin A, significantly increased apoptosis compared with matched controls (P = 0.0018). There were no significant differences between pre- and post-treatment serum levels of prostate-specific antigen, testosterone or biochemical factors or Gleason score in the treated patients ($P > 0.05$). The study was performed in men undergoing radical prostatectomy; however, it indicates that the isoflavones may halt the progression of prostate cancer by inducing apoptosis in low-to-moderate grade tumours (Gleason grade 1–3) (Jarred et al 2002).

Breast cancer

A 2006 systematic review of complementary and alternative therapeutic approaches, including the use of red clover, in patients with early breast cancer drew the conclusion that available data on complementary and alternative medicine modalities in the treatment of early-stage breast cancer does not support their application (Gerber et al 2006).

Benign prostatic hypertrophy

Isoflavone-containing food and supplements are widely used in patients with benign prostatic hypertrophy (BPH). An in vivo study using mice showed that red clover-derived isoflavones have a significant effect on prostatic growth, and are capable of reducing the tendency to enlarged non-malignant prostate, by acting as antiandrogenic agents rather than weak oestrogenic substances (Jarred et al 2003). A case series (n = 29) presented at the Endocrine Society's 82nd Annual Meeting in 2000 suggested that 3 months of treatment with one or two tablets of Trinovin (standardised to 40 mg red clover isoflavones per tablet) significantly decreased nocturia frequency, the International Prostate Symptom Score, increased urinary flow rates and quality of life (QOL) score. The prostate specific antigen (PSA) values and prostate size did not alter from baseline (Ulbricht & Basch 2005). A small clinical trial involving 20 men aged over 65 years with elevated prostate-specific antigen (PSA) levels and negative prostate biopsy findings showed that oral administration of a red clover isoflavone extract (60 mg/day) significantly decreased total PSA levels by >30%. During the 1-year treatment period, active treatment was well tolerated and caused no side effects and significantly increased liver transaminases (an indication of improved liver function) were observed (Engelhardt & Riedl 2008).

Osteoporosis prevention

Pharmaceutical hormone replacement therapy (HRT) is sometimes used for preventing loss of bone following menopause; however, a growing number of users are concerned about the increased risk of breast cancer associated with long-term HRT. As such, phyto-oestrogens have been used as an alternative to prevent osteoporosis. Most research has focused on soy isoflavones, although there is some evidence that red clover-derived isoflavones may also be of benefit.

Animal studies have demonstrated that red clover isoflavones are effective in reducing bone loss probably by reducing of the bone turnover via inhibition of bone resorption (Occhiuto et al 2007). However, human studies show variable results. In a trial by Atkinson et al, loss of lumbar spine bone mineral content and bone mineral density was significantly reduced in women taking red clover-derived isoflavones (43.5 mg/day) compared to placebo in a double-blind, placebo-controlled, randomised trial in 205 women over 12 months (Atkinson et al 2004a). Bone formation markers were also significantly increased; however, no improvement in hip-bone mineral content or bone mineral density was noted. A double-blind study of 46 postmenopausal women investigated the effects of a red clover isoflavone preparation (Rimostil) containing genistein, daidzein, formononetin and biochanin A after a single-blind placebo phase and followed by a single-blind washout phase. Patients were randomly assigned to receive 28.5 mg, 57 mg or 85.5 mg phyto-oestrogens daily for a 6-month period. After the test period, the bone mineral density of the proximal radius and ulna rose significantly, by 4.1% with a dose of 57 mg/day and by 3.0% with a dose of 85.5 mg/day isoflavones. The response with 28.5 mg/day isoflavones was not significant (Clifton-Bligh et al 2001).

No significant difference in bone turnover markers was apparent after 12 weeks of treatment with Promensil and Rimostil in a double-blind, placebo-controlled, randomised clinical trial in 252 menopausal women aged between 45 and 60 years (Schult et al 2004).

OTHER USES

Several human and animal studies have attributed hypolipidaemic, hypoglycaemic or antiatherosclerotic effects to red clover extract or isoflavones. Red clover isoflavones extract exert a neuroprotective effect in human cortical neurons in vitro, which may be due to antioxidant and oestrogenic actions (Occhiuto et al 2008, 2009).

An animal study to investigate the effects of red clover isoflavones on skin ageing, the histology of the skin, skin thickness and the amount of total collagen, with a red clover extract standardised to contain 11% isoflavones concluded that red clover isoflavones are effective in reducing skin ageing induced by oestrogen deprivation (Circosta et al 2006).

TRADITIONAL USES

Red clover flower heads are traditionally used for indications not related to the potential hormonal activity of the herb. The alterative or blood cleansing action is used in skin eruptions and as part of treatment for cancer. A poultice of red clover flowers can be used to soothe local inflammations such as acne, burns or ulcers.

The British Herbal Pharmacopoeia lists red clover as a dermatological agent, mild antispasmodic and expectorant (British Herbal Medicine Association Scientific Committee 1983). The specific indications are for eczema and psoriasis. Red clover is said to combine well with yellow dock for treatment of chronic skin disease.

DOSAGE RANGE

- 4 g as infusion or extract.
- Liquid extract (1:1) in 25% alcohol: 1.5–3.0 mL/day.
- Concentrated isoflavone extract containing 40–80 mg total isoflavones are recommended, based on the daily intake of phytoestrogens in a traditional Japanese diet.

Note: The isoflavone content of the marketed red clover products is highly variable and this alone may significantly affect the absorption rates.

According to clinical reports

- Menopausal symptoms: 40–82 mg daily of red clover-derived isoflavones.
- Lipid lowering: 40–86 mg daily of red clover-derived isoflavones.
- Osteoporosis prevention: 44–86 mg daily of red clover-derived isoflavones.
- BPH symptom relief: 40–80 mg daily of red clover-derived isoflavones.

ADVERSE REACTIONS

The oestrogenic potency of the isoflavones has been well documented. Overgrazing cattle or sheep on red clover can be detrimental to their fertility. In 'clover disease', ewes are made permanently infertile by clover consumption. In animals with clover disease, the uterine response to oestrogen is reduced, as is the surge in LH. Clover disease has not been observed with normal therapeutic doses in humans. None of the trials has reported adverse effects. An isoflavone preparation from soy bean, and red clover extracts containing genistein, daidzein, biochanin A and formononetin, did not modify the endometrial architecture in 25 postmenopausal women taking the preparation for 1 year (Aguilar et al 2002).

SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

Anticoagulant agents

Red clover contains coumarin, which could theoretically exert anticoagulant activity and therefore increase the clinical effects of warfarin. However, it is only the byproduct, dicoumarol (produced by microorganism in poorly dried sweet clover), that has established anticoagulant effects. However, interaction with anticoagulant medication is not likely for extracts from properly dried red clover. Observe patients taking red clover and anticoagulants concurrently.

Oestrogens

Theoretically, if taken in large quantities, phytoestrogens may compete with synthetic oestrogens for receptor binding, but the clinical significance of this remains unknown. A recent review concluded that up to 2 mg of red clover-derived isoflavones per kg should be considered a safe dose for most patient groups (Barnes 2003).

CONTRAINDICATIONS AND PRECAUTIONS

There are no known contraindications for the flower head extracts. Concentrated isoflavone extracts should only be used by people with oestrogen-sensitive cancers under professional supervision because of the possible proliferative effects. Additionally, people with conditions that may be aggravated by increased oestrogen levels, such as endometriosis or uterine fibroids, should use this herb under professional supervision only. Importantly, no randomised controlled trials have addressed the long-term safety of phytoestrogens in patients after a diagnosis of breast cancer (Boekhout et al 2006).

Red clover isoflavones are well tolerated in healthy women according to a 3-year study of 400 women. Supplements containing red clover isoflavones did not adversely affect breast density, skeletal strength or cardiovascular status. In postmenopausal women, endometrial status was not adversely affected. The adverse event profile was similar between red clover isoflavones, and placebo and endocrine status did not differ (Powles et al 2008).

PREGNANCY USE

Scientific evidence for the use of red clover during pregnancy has not been established. No teratogenicity data are available — use is not recommended.

PRACTICE POINTS/PATIENT COUNSELLING

- Red clover flower heads are traditionally considered a dermatological agent, mild antispasmodic and expectorant and specifically used for eczema and psoriasis. In practice, it is often combined with yellow dock for treatment of chronic skin disease.
- In recent years, red clover isoflavones have been studied and shown to have an affinity for oestrogen alpha- and beta-receptors and may act as both agonists and antagonists, depending on the level of endogenous oestrogens.
- Evidence that red clover-derived isoflavones reduce hot flush frequency in menopause is unconvincing.
- Preliminary evidence suggests a possible preventative role in osteoporosis; however, further research is required.
- Concentrated isoflavone extracts from red clover are used in cardiovascular disease as there is weak evidence that it may reduce arterial stiffness, increase HDL cholesterol and decrease triglycerides.
- Evidence from animal studies and case series suggests a potential role in BPH.
- There is weak evidence that red clover isoflavone extracts may reduce risk of hormone-sensitive cancers and that they may be beneficial in the treatment of prostate cancer.

PATIENTS' FAQS

What will this herb do for me?

Red clover is traditionally used for skin disorders. In recent years, concentrated red clover isoflavone extracts have been promoted for use in the treatment of menopausal symptoms, although clinical studies are inconsistent and generally unsupportive.

When will it start to work?

Red clover tea or extract for skin diseases requires long-term use. Improvement may occur within several weeks with the condition continuing to improve with long-term use. Improvement in menopausal symptoms from the use of concentrated isoflavone extracts may take 2–3 months, although results are inconsistent.

Are there any safety issues?

Short- or long-term use of red clover tea or flower head extract is not thought to be associated with any adverse reactions and its use is considered safe. Concentrated red clover isoflavone extracts may have subtle oestrogenic activity and little is known about drug interactions or long-term use. As a result, they should not be used by people with oestrogen-sensitive tumours or conditions that may be aggravated by increased oestrogen levels such as endometriosis, unless under professional supervision. People with breast cancer should only use red clover extracts under professional supervision.

Red yeast rice

HISTORICAL NOTE Red yeast rice, also known as red Koji or 'Hongqu', is a dietary staple in many Asian countries, including China and Japan, and has been used as a food, medicine and seasoning for more than a thousand years. Li Shizhen, the great pharmacologist of the Ming Dynasty (1368–1644), reported that 'Hongqu' promotes 'digestion and blood circulation, and can strengthen the spleen and dry the stomach' (Ma et al 2000). Red yeast rice, which is produced by fermenting steamed, non-glutinous rice with *Monascus* species of food fungus, is widely used in making pickled tofu, for brewing rice wine and as a preservative for meat and fish, thereby giving many dishes such as Peking duck their characteristic red colour.

In recent years, several commercial versions of red yeast rice have been made available and red yeast rice has been included by the Chinese Ministry of Health into food additive standards to increase the colour and delicacy of meat, fish, and soybean products. In 1979, Prof Akira Endo, working in Japan on fungicides, found that *Monascus purpureus* on rice contained a compound that he called 'Monacolin K', which was identified as a new hypocholesterolaemic agent that specifically inhibits HMG-CoA reductase (Endo 1980). This discovery led to the development of a new class of anticholesterol drugs now called the 'statins'.

COMMON NAME

Red yeast rice (RYR)

OTHER NAMES

Chinese red yeast rice, Red Koji, Hongqu, Hon-Chi, Beni-koji. Zhi Tai is the dried, powdered form while Xue Zhi Kang is a standardised ethanolic extract.

BOTANICAL NAME/FAMILY

RYR is produced by fermenting cooked rice with various *Monascus* species, most commonly *Monascus pilous* and *Monascus purpureus*.

CHEMICAL COMPONENTS

RYR is a food and medicine with a range of potentially active and synergistic constituents. While it is assumed that the main active constituents are the monacolins, particularly monacolin K or lovastatin along with a range of other monacolins, there are a number of other potentially active constituents such as plant sterols, isoflavones and isoflavone glycosides, pigments, tannins and other phytochemicals that may act synergistically to produce clinical effects. This is evident by the finding that the cholesterol-lowering effect of RYR is greater than that of an equivalent dose of lovastatin (Li Z et al 2005b).

The monacolin content of traditionally produced RYR has been found to vary widely (Huang et al 2006, Li et al 2004). This may be due to variations in *Monascus* species, growing and storage conditions, as monacolin levels are influenced by exposure to light and heat (Li YG et al 2005). A study that examined the chemical constituents of nine different commercially available RYR supplements found that total monacolin content varied from 0% to 0.58% w/w and that only one of nine preparations had the full complement of 10 different monacolin compounds (Heber et al 2001).

As a fermented food, RYR may contain differing levels of the hazardous mycotoxin, citrinin, which has been found at measurable concentrations in seven of nine commercial preparations (Wong & Rabie 2008). Modern production methods aim to standardise the monacolin content and minimise the citrinin content (Soo et al 2007).

MAIN ACTIONS

Cholesterol lowering

RYR has significant lipid-lowering activity which is due to multiple mechanisms. One of the most studied is inhibition of HMG-CoA reductase.

Inhibition of HMG-CoA reductase, which is the rate-limiting enzyme in cholesterol biosynthesis, causes a decrease in cholesterol synthesis, which leads to up-regulation of LDL receptors, increasing the rate of removal of LDL from plasma. RYR contains natural statin components that inhibit HMG-CoA reductase and hence reduce cholesterol synthesis in human hepatic cells in a dose-dependent manner (Man et al 2002).

RYR has also been found to reduce serum total cholesterol and triglycerides in rabbits and quails with experimental hyperlipidaemia and suppress atherosclerosis induced by atherogenic diets (Li et al 1997). The authors of this study suggest that the lipid-lowering mechanism of red yeast rice is not completely understood and may be due to the

combination of its total constituents exerting multiple mechanisms including inhibiting in vivo biosynthesis of cholesterol, preventing the absorption of ingested cholesterol, or increasing cholesterol clearance from the circulation.

In animal studies, RYR significantly reduces serum lipids and the severity of atherosclerosis in rabbits fed for 200 days on a semi-purified diet containing 0.25% cholesterol. Treatment resulted in a significant reduction in atherosclerotic index (ratio of non-HDL cholesterol to HDL cholesterol). Interestingly, although similar reductions of total, LDL cholesterol and triglycerides were observed in a parallel group of rabbits fed 2.4 mg/kg/day of lovastatin, the lovastatin group did not have a significant reduction in atherosclerotic index (Wei et al 2003).

As well as reducing cholesterol, RYR may also have positive effects on endothelial function by reducing homocysteine-stimulated endothelial adhesiveness, as well as down-regulating intracellular reactive oxygen species (ROS) formation (Lin et al 2008). It has also been observed that RYR extract (Xuezhikang) significantly enhanced proliferation and adhesion capacity of endothelial progenitor cells derived from the peripheral blood of patients with stable coronary artery disease to the same extent as atorvastatin (Kong et al 2008).

Anti-inflammatory

Recent studies suggest that in addition to lowering cholesterol, the statin drugs may have potent vascular anti-inflammatory actions that produce reductions in vascular plaque adherence and migration to sites of inflammation in atherosclerosis. This has led to the suggestion that low-dose statins may be used for long-term treatment of cardiovascular disease in susceptible individuals (Liao 2004). Interestingly, trials have demonstrated anti-inflammatory properties for RYR. In a randomised controlled trial involving 36 patients with cardiovascular disease, 1200 mg/day of a RYR extract (Xuezhikang) was found to significantly reduce C-reactive protein (CRP) and other inflammatory markers and prolong exercise tolerance and time to 1-mm ST-segment depression, in addition to significantly reducing total cholesterol, LDL cholesterol and triglycerides (Li et al 2007). Similarly, the same extract was found to produce significant reductions in CRP within 24 hours (Li JJ et al 2005a), reduce CRP levels and improve preprandial and postprandial endothelial function after 6 weeks in patients with coronary heart disease (Liu et al 2003, Zhao et al 2004). These findings have led to the suggestion that the inclusion of RYR in Asian diets may contribute to the median CRP level of Asians being only one-tenth that of Westerners (Kao et al 2006).

Anticancer

Epidemiological studies demonstrate that individuals taking statins have a reduced risk of colon cancer. RYR and lovastatin have been shown to inhibit tumour cell growth and enhance apoptosis in human colon cancer cells. However, it is suggested that RYR may have anticancer activity, additional to those conferred by its statin content, as lovastatin-induced tumour inhibition was found to be reversed by mevalonate while RYR-induced inhibition was not. This has led to the suggestion that other components in RYR, including other monacolins, pigments or the combined matrix effects of multiple constituents, may affect intracellular signalling pathways differently from lovastatin (Hong et al 2008a, 2008b) This suggestion is supported by a study on prostate cancer cells, which found that RYR showed a more potent inhibition effect on prostate cancer cell growth compared to lovastatin (Hong et al 2008b).

Osteogenesis

Statins have recently been shown to stimulate bone formation and RYR preparations have also been shown to produce strong bone anabolic effects, both in vitro and in vivo (Gutierrez et al 2006, Wong & Rabie 2008). The ability of flavonoids and statins that occur naturally in food products to promote bone formation has led to the suggestion that RYR may provide a dietary intervention to stimulate bone formation and prevent osteoporosis (Mundy 2006).

Antidiabetic

Oral administration of RYR decreased plasma glucose and delayed the development of insulin resistance in rats fed a fructose-rich diet, as well as improved insulin sensitivity in streptozotocin-induced diabetic rats (Su et al 2007). RYR has also been shown to attenuate the elevation of plasma glucose induced by an intravenous glucose challenge test in normal rats and reverse hyperphagia in streptozotocin-diabetic rats (Chang et al 2006). Further rat studies suggest that the plasma glucose-lowering action of RYR is due to release of acetylcholine and subsequent stimulation of muscarinic M3 receptors in pancreatic cells that effect insulin release (Chen & Liu 2006) as well as decrease hepatic gluconeogenesis to lower plasma glucose in diabetic rats lacking insulin (Chang et al 2006).

CLINICAL USE

Hyperlipidaemia

In addition to empirical use over hundreds of years attesting to its safety and efficacy, there are at least 100 randomised controlled trials of RYR products. A recent meta-analysis of 93 RCTs on three RYR preparations (Cholestin, Xuezhikang and Zhibituo), which included 9625 participants, found significant reduction of serum total cholesterol levels, triglycerides levels and LDL cholesterol levels, and increase of HDL cholesterol levels with RYR supplementation compared with placebo. These studies found that the lipid modification effects of RYR are similar to that of statin medications and that RYR was generally safe and well tolerated. When compared with non-statin lipid-lowering agents, RYR preparations appeared superior to nicotinate and fish oils, but equal to or less effective than fenofibrate and gemfibrozil (Liu et al 2006).

A multicentre, placebo-controlled trial of a partially purified extract of red yeast rice (Xuezhikang), involving 4870 patients, found that 4.5 years of

supplementation lowered total and low-density lipoprotein cholesterol and triglycerides, and raised high-density lipoprotein cholesterol levels. This study also found a relative risk reduction of 45% and an absolute risk reduction of 4.7% for coronary events, along with a 33% reduction in total mortality in those taking the RYR extract. Interestingly, this study also found a marked 45% reduction of cancer-related deaths (Lu et al 2008). A substudy involving 591 diabetic patients from the same group found even more dramatic results with a 50% reduction in cardiovascular events and a 44% reduction in overall mortality in the patients taking RYR compared to those taking placebo (Zhao et al 2007).

In a small randomised, double-blind, placebo-controlled pilot study involving 14 adults with dyslipidaemia related to HIV, RYR supplementation for 8 weeks was found to lower total and low-density lipoprotein cholesterol without any adverse effects (Keithley et al 2002).

OTHER USES

It has been suggested that in addition to reducing cholesterol, it is possible that monacolins could prevent stroke and reduce the development of peripheral vascular disease. This class of molecules have antithrombotic and anti-inflammatory effects, which may offer protection against atherosclerotic plaque growth as well as being used for the treatment of hypertension, osteoporotic fractures, ventricular arrhythmia and immune response (Manzoni & Rollini 2002).

DOSAGE RANGE

RYR is a dietary staple in many Asian countries with typical consumption ranging from 14–55 g/person/day. The average dose of RYR products is 2.4 g/day depending on the product used.

ADVERSE REACTIONS

The recent meta-analysis revealed that, of the 77 controlled trials that reported adverse events, there were no serious adverse events reported, while non-serious adverse effects were limited to dizziness, low appetite, nausea, stomach ache, abdominal distention and diarrhoea, with a small proportion of participants having increased serum blood urea nitrogen and alanine aminotransferase levels (ALT) (Liu et al 2006).

The American College of Cardiology Task Force on integrating complementary medicine into cardiovascular medicine suggested that RYR should be 'treated as an HMG-CoA reductase inhibitor, with all the possible side effects, drug interactions, and precautions associated with this class of drugs' (Vogel et al 2005). While the statin drugs are used extensively throughout the world and are generally recognised as safe, they have the potential to reduce endogenous production of CoQ10 and cause rhabdomyolysis.

A number of cases of statin-like muscle damage that may be related to very low CoQ10 levels have been reported in patients taking red yeast rice (Smith & Olive 2003, Vercelli et al 2006), and animal studies have demonstrated a dose-dependent reduction in CoQ10 levels with high levels of RYR (Yang et al 2005).

SIGNIFICANT INTERACTIONS

Statin drugs

RYR products contain low doses of natural statins and, as such, a pharmacodynamic interaction is possible with other statin medications.

Cyclosporin and P450 inhibitors

Monacolins are metabolised by the cytochrome P450 system and therefore cyclosporin and other P450 inhibitors have the potential to increase the risk of rhabdomyolysis (Prasad et al 2002).

Coenzyme Q10

Similar to statin medications, RYR may reduce endogenous production of CoQ10 — concurrent supplementation with CoQ10 may be worth considering with long-term use of RYR.

CONTRAINDICATIONS AND PRECAUTIONS

Patients with statin-induced muscle damage should be advised against using RYR (Vercelli et al 2006).

PREGNANCY USE

Insufficient reliable information is available to confirm safety in pregnancy. Safety unknown.

PRACTICE POINTS/PATIENT COUNSELLING

- RYR is a complex whole food substance that has long traditional use as a food and medicine and is still a common feature of Asian diets.
- RYR has been found to contain monacolins (statins) which are used to lower cholesterol and reduce the risk of cardiovascular disease. RYR may also have anti-inflammatory, anti-cancer and bone-forming properties.
- There are differences between different RYR products, some of which are standardised to statin content.
- RYR products should be stored away from heat and light.

PATIENTS' FAQs

What will this supplement do for me?

RYR can be used to lower cholesterol levels and reduce the risk of atherosclerosis. It may also have beneficial effects for people with diabetes, osteoporosis, inflammatory disease and cancer.

When will it start to work?

Effects may be noticed immediately with full cholesterol lowering effects being evident after 6–8 weeks.

Are there any safety issues?

RYR may have rare adverse effects similar to the statin medications, such as unexplained muscle pain and weakness that can lead to kidney damage.

Rhodiola

HISTORICAL NOTE Rhodiola is a popular herb in the traditional medicine of Eastern Europe, Asia and Scandinavia where it has been used to stimulate the nervous system, enhance physical and mental performance and improve resistance to high-altitude sickness (van Diermen et al 2009). It grows in high-altitude Arctic regions of Europe and Asia (Goel et al 2006) and is reported to have been used by the Vikings to enhance physical strength and endurance (Darbinyan et al 2007). It is also mentioned by Dioscorides as early as the first century AD. Rhodiola has been categorised as an 'adaptogen' in traditional systems due to its ability to increase resistance to a variety of chemical, biological and physical stressors; and is noted for its antidepressant, anticancer and cardioprotective properties (Kelly 2001). It has a reputation for improving depression, enhancing work performance, eliminating fatigue and treating symptoms of debility following intense physical and psychological stress (Perfumi & Mattioli 2007).

OTHER NAMES

Arctic root, golden root, Hongjingtian, king's crown, Lignum rhodium, rose root, Russian rhodiola, Siberian golden root

BOTANICAL NAME/FAMILY

Rhodiola rosea (family Crassulaceae)

A number of rhodiola species can be identified in the scientific literature and may possess varying pharmacological activities, chemical constituents and efficacy in clinical application (Kucinskaite et al 2007, Li & Zhang 2008). These include: the Indian herb *rhodiola imbricata* (Goel et al 2006) and the Tibetan herb *rhodiola sacra* (Shih et al 2008), *rhodiola quadrifida* (Skopnska-Rozewska et al 2008), *rhodiola sachalinensis* (Wu et al 2008), *rhodiola crenulata* (Song et al 2008) and *rhodiola dumulosa* (Liu et al 2008).

PLANT PART USED

Root

CHEMICAL COMPONENTS

Salidroside (aka rhodiolosides A-F; monoterpene glycosides), and their aglycones; rhodiolol A, rosiridol and sachalinol A (Ali et al 2008, Li W et al 2008, Li HB et al 2008, Ma et al 2006, Yu et al 2008); rosavins (rasavin, rosin, rosarin; phenylpropanoids) (Kucinskaite et al 2007); gossypetin-7-O-L-rhamnopyranoside, rhodioflavonoside, gallic acid, trans-p-hydroxycinnamic acid and p-tyrosol (Ming et al 2005); cinnamic alcohol, cinnamaldehyde and cinnamic acid (Panossian et al 2008); hydroquinone (Wang et al 2007). The balance of rosavins to salidrosides is usually 3:1.

MAIN ACTIONS

Adaptogenic (modulates stress response)

Prolonged exposure to stressful life events and depression may contribute to significant behavioural, endocrinological and neurobiological changes in both humans and animals. Animal studies have suggested that chronic administration of rhodiola extract (standardised to 3% rosavin and 1% salidroside; 10, 15 and 20 mg/kg by gavage) results in potent inhibition of the behavioural and physiological changes induced by chronic exposure to mild stressors in a manner comparable to those of fluoxetine (oral 10 mg/kg) (Mattioli et al 2009). Other studies suggest an ability to selectively attenuate stress-induced anorexia (Mattioli & Perfumi 2007). In experimental studies, extracts of rhodiola appear to increase stress resistance and contribute to a longer lifespan. The extract induces translocation of the DAF-16 transcription factor from the cytoplasm into the nucleus, suggesting a reprogramming of transcriptional activities favouring the synthesis of proteins involved in stress resistance and longevity (Wiegant et al 2009).

Single-dose studies of rhodiola extract (standardised to 3% rosavin and 1% salidroside; 10, 15 and 20 mg/kg) have demonstrated antidepressant, adaptogenic, anxiolytic and stimulating effects in mice (Perfumi & Mattioli 2007). In addition, rhodiola has been reported to prevent catecholamine release and subsequent cyclic AMP elevation in the myocardium, and the depletion of adrenal catecholamines induced by acute stress in vivo (Maslova et al 1994). According to Panossian (2005), the beneficial effects of multidose administration of adaptogens, such as rhodiola, are mainly associated with the hypothalamic–pituitary–adrenal (HPA) axis, while single-dose applications are more useful in situations that require a rapid response to tension or to a stressful situation via the sympatho-adrenal-system (SAS). Rhodiola exerts a stimulating effect within 30 min of administration that continues for approximately 4–6 h. This activity appears to be due to salidroside and rosavin (Panossian & Wagner 2005).

Improved physical performance

While earlier animal studies seemed promising (Abidov et al 2003, Azizov & Seifulla 1998), rhodiola has produced mixed results when attempting to demonstrate an ergogenic effect during exercise in humans (Walker & Robergs 2006). Rhodiola is purported to enhance physical performance, possibly by improving adenosine triphosphate (ATP) turnover; however, several small-scale human trials have failed to confirm these effects. In a placebo-controlled trial 12 resistance-trained men received rhodiola (1500 mg/day) or placebo for 4 days. After completing incremental forearm wrist flexion exercise to volitional fatigue no significant improvements were demonstrated for time to exhaustion or recovery (Walker et al 2007). A combination formula containing rhodiola also failed to demonstrate significant effects on muscle tissue oxygen saturation, $VO_{2max,}$ ventilatory threshold or time to exhaustion in a placebo-controlled study involving eight participants (Colson et al 2005). Single-dose administration of rhodiola extract (200 mg standardised to 3% rosavin and 1% salidroside) may prove to be more promising with earlier studies showing benefits in time to exhaustion (16.8 ± 0.7 min to 17.2 ± 0.8 min; $P < 0.05$), VO_{2peak} and $VCO_{2peak,}$ and also possibly pulmonary ventilation ($P = 0.07$) (124.8 ± 7.7 L/min versus 115.9 ± 7.7 L/min) (De Bock et al 2004). Rhodiola also exhibits anti-inflammatory activity and protects muscle tissue from damage during exercise according to a study involving healthy untrained volunteers who performed exhausting exercise (Abidov et al 2004).

Improved mental performance

It has been suggested that rhodiola extract promotes the release of monoamine neurotransmitters in the ascending pathways of the brainstem thus activating the cerebral cortex and limbic system. As a result, cognitive function, attention, memory and learning may be enhanced (Panossian & Wagner 2005). Animal experiments have demonstrated improvements in learning and retention after 24 h following a single dose (0.10 mL/rat) and long-term memory after 10 days treatment at the same dose. Higher (1.0 mL) and lower (0.02 mL) doses did not appear to be effective (Petkov et al 1986).

In the 1960s, Zatova demonstrated that a single dose of *R. rosea* extract could improve mental performance. Eighty-five healthy males and females, aged 20–28 years old working under the same conditions, were studied using Anfimov's table (which provides numerically comparable data characterising the quality and quantity of work performed). Doses of 5–10 drops were found to be the most effective, reducing the number of errors by an average of 46%. At a dose of five drops, the rhodiola extract led to a reduction in the number of errors in 88% of the subjects tested, but to an increase in the remaining 12%; in comparison to placebo which produced a reduction in the number of errors in 35% of the subjects, an increase in 58% and no change in the remaining 7% (Panossian & Wagner 2005).

During a 12-week study, the efficacy and safety of rhodiola extract given in combination with vitamins and minerals (vigodana®) was tested in 120 adults (83 women and 37 men, aged 50–89 years) with physical and cognitive deficiencies (Fintelmann & Gruenwald 2007). Two different dosage regimens were chosen: 2 capsules orally in the morning after breakfast, or 1 capsule after breakfast and 1 after lunch. A statistically significant improvement ($P < 0.001$) in physical and cognitive performance was observed in both groups but was more pronounced in the group taking both capsules after breakfast. No adverse events occurred during the course of the study (Fintelmann & _Gruenwald 2007). While the results of this study are promising, they need to be confirmed by more rigorously designed placebo-controlled clinical trials of rhodiola alone.

Anticholinesterase

Spectral methods (NMR, UV and MS) have identified a strong anticholinesterase activity for hydroquinone, a component of rhodiola (Wang et al 2007).

Antidepressant

Rhodiola is one of the more promising herbal medicines for the treatment of monopolar depression (Kelly 2001, Kucinskaite et al 2004, Sarris 2007). It appears to influence the levels and activity of monoamine neurotransmitters such as serotonin, noradrenalin and dopamine (Stancheva & Mosharrof 1987). Recently, extracts of rhodiola exhibited potent anti-depressant activity by inhibiting monoamine oxidase (MAO)-A in vitro which may partly explain its effects (van Diermen et al 2009). It is suspected that rhodiola also facilitates neurotransmitter transport within the brain (Stancheva & Mosharrof 1987). Other studies indicate that antidepressant effects are likely due to salidroside on stress-activated protein kinases (SAPK), which play a key role in HPA axis overactivity by inhibiting the sensitivity of glucocorticoid receptors to cortisol (Darbinyan et al 2007).

Immunomodulation

While studies using rhodiola alone for immune modulation could not be located, several polyherbal preparations containing rhodiola have been tested producing good results. In a placebo-controlled trial, a combined preparation known as Admax® (Nulab Inc) containing *rhodiola rosea* in combination with *Eleutherococcus senticosus*, *Schisandra chinensis* and *Leuzea carthamoides* (270 mg/day) was given to 28 patients with stage III–IV epithelial ovarian cancer receiving a one-off dose of cisplatin (75 mg/m^2) and cyclophosphamide (600 mg/m^2). Subjects received treatment or placebo for 4 weeks. In patients who took Admax, the mean numbers of four T cell subclasses (CD3, CD4, CD5 and CD8) and the mean amounts of IgG and IgM were increased suggesting attenuation of the suppressed immunity experienced by ovarian cancer patients undertaking chemotherapy (Kormosh et al 2006). Additionally, a double-blind, placebo-controlled, randomised trial of Chisan® (a standardised combination of *rhodiola rosea*, *Schisandra chinensis* and *Eleutherococcus senticosus*) was carried out on 60 patients receiving cephazoline, bromhexine and theophylline for acute non-specific pneumonia. The addition of Chisan twice daily for 10–15 days in the treatment group resulted in a 2-day reduction in the mean time required to bring about recovery from the acute phase and improved quality-of-life (QOL) scores during convalescence (Narimanian et al 2005).

Antibacterial

The methanolic extract of rhodiola root has been shown to inhibit the activity of *Staphylococcus aureus* in Microbial Sensitivity Tests. The active compounds were identified as gossypetin-7-O-L-rhamnopyranoside and rhodioflavonoside at concentrations of 50 microgram/mL and 100 microgram/mL, respectively (Ming et al 2005).

Cardioprotective

Rhodiola extract has been shown to exert cardioprotective effects in vivo. More specifically, rhodiola extract demonstrates protection against reperfusion injury after ischaemia, antiarrhythmic activity and increases serum levels of beta-endorphin and leu-enkephalin in myocardial tissue. The effects appear to be dependent on the occupancy of opioid receptors by endogenous opioid peptides (Maslov & Lishmanov 2007). Oral administration of rhodiola rosea extract (3.5 mg/kg) also appears to have a favourable effect on heart contractility and coronary flow parameters due to an increase in the level of endogenous opioid peptides (Lishmanov et al 1997). The anti-arrhythmic effect of rhodiola extract is a result of activation of both central and peripheral opioid receptors (Maimeskulova & Maslov 2000) and stimulation of kappa-OR (Maimeskulova et al 1997). It is suspected that herbal treatment increases endogenous production of opioids.

Combination preparations, such as tonizid (containing *rhodiola rosea* in combination with *Aralia mandshurica*, *Panax ginseng* and *Eleutherococcus senticosus*), have also demonstrated cardioprotective and antifibrillatory properties during acute cardiac ischaemia/reperfusion and postinfarction cardiac fibrosis (Arbuzov et al 2006, Lishmanov et al 2008).

OTHER ACTIONS

Antioxidant

Rhodiola extract reduces oxidative stress in vitro (Battistelli et al 2005) and increases endogenous antioxidant production in vivo. Rhodiola was able to significantly protect human erythrocytes from glutathione (GSH) depletion, glyceraldehyde-3-phosphate dehydrogenase (GAPDH) inactivation and haemolysis induced by the oxidant hypochlorous acid (HOCl), in a dose-dependent manner (De Sanctis et al 2004). In animal studies, rhodiola extract (200 mg/kg/day for 12 weeks) increased the levels of reduced glutathione and the activity of glutathione reductase, glutathione S-transferase, glutathione peroxidase, catalase and superoxide dismutase in the liver (Kim et al 2006). In human trials, a trend towards decreased lipid peroxidation has been observed following 7-day treatment with rhodiola rosea (Wing et al 2003).

Antidiabetic

Rhodiola extract (200 mg/kg/day for 12 weeks) significantly decreases blood glucose and lipid peroxidation in vivo. It also increases levels of reduced glutathione and the activity of glutathione reductase, glutathione S-transferase, glutathione peroxidase, catalase and superoxide dismutase in the liver (Kim et al 2006). Further in vivo studies have revealed that water-soluble rhodiola extract inhibits alpha-glucosidase and pancreatic alpha-amylase (Apostolidis et al 2006). Ethanolic extracts also inhibit alpha-amylase, alpha-glucosidase and also angiotensin-converting enzyme (ACE) (Kwon et al 2006). The effect appears to be dependent on the phenolic content and profile (Apostolidis et al 2006, Kwon et al 2006). In experimental studies, salidroside, one of the major active components of rhodiola, has a dose-dependent effect on glucose transport activation and insulin sensitivity via AMP-activated protein kinase (AMPK) activation (Li HB et al 2008) and may inhibit lipid peroxidation (Zhang & Liu 2005).

Neuroprotective

Salidroside, an isolated component of rhodiola, has demonstrated a dose-dependent neuroprotective effect in animal models (Bocharov et al 2008). Salidroside has protective effects against oxidative stress-induced cell apoptosis (Zhang et al 2007), inhibits intracellular reactive oxygen species (ROS) production and restores mitochondrial membrane potential (Yu et al 2008) and decreases intracellular free calcium concentration (Zhang et al 2004). As a result, salidroside may warrant further investigation for preventing and treating cerebral ischaemic and neurodegenerative diseases (Yu et al 2008).

Ctyoprotective

Salidroside, extracted from *rhodiola rosea*, may protect PC12 cells against glutamate excitotoxic damage through suppressing the excessive entry of calcium and the release of the calcium stores (Cao et al 2006).

Hepatoprotective

Hepatoprotective effects have been demonstrated in rats with experimental toxic hepatitis: normalising the activity of aspartate aminotransferase (AST) and alkaline phosphatase (ALP); reducing the activity of alanine aminotransferase (ALT) and glutathione-S-transferase; and normalising the content of medium-molecular-weight peptides, urea and bilirubin in plasma (Iaremii & Grigor'eva 2002). Rhodiola extract has also been shown to reduce the liver dysfunction associated with adriamycin (an anthracycline antibiotic) in mice without affecting the drug's antitumour activity (Udintsev et al 1992).

Anticancer effects (antimutagenic, cytostatic, antiproliferative, antimetastatic)

Rhodiola extract seems to have anticancer activity according to test tube and animal studies, which is due to a combination of mechanisms. rhodiola rosea extracts reduce experimentally induced mutations, most likely due to increased efficiency of intracellular DNA repair mechanisms (Salikhova et al 1997). The cytostatic and antiproliferative effects of rhodiola extract have been demonstrated in experimental models. Rhodiola has been shown to inhibit the division of HL-60 cells leading to induction of apoptosis and necrosis, and to a marked reduction in their survival. After treatment with the extract, no chromosome aberrations or micronuclei were observed (Majewska et al 2006). Antiproliferative and antimetastatic effects have been noted in animal models of Pliss lymphosarcoma (Udintsev & Shakhov 1991b). A decrease of cyclophosphamide haematotoxicity by rhodiola rosea root extract in mice with Ehrlich and Lewis transplantable tumours has also been demonstrated (Udintsev & Schakhov 1991a).

In a small human trial, oral administration of rhodiola extract to 12 patients with superficial bladder carcinoma (T1G1-2) resulted in improvements in urothelial tissue integration, parameters of leukocyte integrins and T-cell immunity. A non-significant reduction in the average frequency of relapse was also noted (Bocharova et al 1995).

CLINICAL USE

Stress and fatigue

Three double-blind studies indicate that treatment with rhodiola extract (SHR-5) has significant antifatigue effects, whereas one study was inconclusive. The most studied extract to date for these indications is SHR-5.

A 28-day course of rhodiola extract SHR-5 (576 mg extract/day) demonstrated a significant antifatigue effect that increases mental performance, particularly the ability to concentrate, and decreases cortisol response to awakening stress in burnout patients with fatigue syndrome (Olsson et al 2008). The randomised, double-blind, placebo-controlled study involved 60 volunteers aged between 20 and 55 years with fatigue syndrome who were randomised to receive four tablets daily of SHR-5 extract (576 mg extract/day) or four placebo tablets daily. Previously, in a randomised, double-blind, placebo-controlled, parallel-group

study, single doses of standardised rhodiola extract (SHR-5) were administered to 161 cadets aged 19–21 years. A highly significant antifatigue effect using the antifatigue index (AFI) was demonstrated for both standard (9 mg/day salidroside) and high dose (13.5 mg/day salidroside) regimens (Shevtsov et al 2003). Repeated low-dose treatment of the standardised extract SHR-5 (standardised to 4.5 mg/day of salidroside) was also tested in a double-blind, crossover trial of 56 young, healthy doctors during night duty. The study also demonstrated a statistically significant antifatigue effect resulting in improvements in the overall level of mental fatigue, concentration and speed of audio–visual perception during the first 2-week period of the crossover study. Following a 2-week washout period, the second treatment group did not experience the same benefits which may have been due to them having been on night duty for a longer period (Darbinyan et al 2000). The same extract (SHR-5) was also used in a double-blind, randomised, placebo-controlled trial of foreign students during a stressful examination period. A repeated low-dose regimen was administered for 20 days resulting in significant improvements in physical fitness, mental fatigue and neuro-motoric tests ($P < 0.01$). Average examination results were also higher in the treatment group (Spasov et al 2000).

Depression

Several studies with experimental models have shown that rhodiola exhibits significant antidepressant activity and in vitro tests provide plausible mechanisms of action (Panossian & Wagner 2005, Perfumi & Mattioli 2007). In one study, rhodiola exhibited a stronger antidepressant effect than either imipramine (30 mg/kg) or *Hypericum perforatum* (20 mg/kg). Rhodioloside and tyrosol were identified as active principles (Panossian et al 2008). Despite this encouraging preliminary evidence, clinical investigation has only just begun.

In a randomised, double-blind, placebo-controlled study with parallel groups conducted over 6 weeks, 89 participants, male and female, aged 18–70 years were selected according to Diagnostic and Statistical Manual of Mental Disorders (DSM)-IV diagnostic criteria for mild-to-moderate depression (Darbinyan et al 2007). The severity of the depression was determined by scores gained in the Beck Depression Inventory (BDI) and Hamilton Rating Scale for Depression (HAMD) questionnaires. Patients with initial HAMD scores between 21 and 31 were randomised to receive either rhodiola rosea extract SHR-5 (340 mg/day) or SHR-5 (680 mg/day) or placebo. At the end of the 6-week trial, participants in both treatment groups experienced significant improvements ($P < 0.0001$) in overall depression, insomnia, emotional instability and somatisation compared to the placebo group. The high-dose group also experienced improvements in self-esteem. There was a dose-dependent effect for the BDI but not for the HAMD and no serious side effects were reported in any of the groups (Darbinyan et al 2007). As a result, rhodiola may represent a useful therapy for the treatment of depression due to glucocorticoid resistance following stressful life events and may be a safer alternative to St John's wort with its potential drug interactions.

Generalised anxiety disorder

In a small pilot study, 10 participants aged 34–55 years were selected according to DSM-IV diagnostic criteria for generalised anxiety disorder (GAD). Participants received rhodiola extract (340 mg/day) for 10 weeks after which time there was a significant decrease in mean Hamilton Anxiety Rating Scale (HARS) scores. Only mild-to-moderate adverse effects were noted, most commonly dizziness and dry mouth, and no drug interaction was observed in the three patients taking benzodiazepines (Bystritsky et al 2008). Larger well-designed trials should be conducted to confirm these effects.

Improved physical performance

There is conflicting evidence on the effect of roseroot for improving athletic performance. While earlier animal studies seemed promising (Abidov et al 2003, Azizov & Seifulla 1998), rhodiola has produced mixed results when attempting to demonstrate an ergogenic effect during exercise in humans (Walker & Robergs 2006).

In a placebo-controlled trial, 12 resistance-trained men, aged 19–39 years, completed an incremental forearm wrist flexion exercise to fatigue, after ingesting rhodiola (1500 mg/day) or placebo for 4 days. There were no significant differences between groups for time to exhaustion or recovery (Walker et al 2007). Similarly, a double-blind, randomised, placebo-controlled trial of a traditional Chinese medicine combination containing *rhodiola rosea* and *Cordyceps sinensis* also failed to demonstrate significant effects on muscle tissue oxygen saturation, VO_{2max}, ventilatory threshold or time to exhaustion (Colson et al 2005).

Conversely, an earlier double-blind, placebo-controlled study had demonstrated beneficial effects with acute but not with chronic dosing of rhodiola. A single dose of rhodiola extract (200 mg standardised to 3% rosavin and 1% salidroside) significantly increased time to exhaustion (16.8 ± 0.7 min to 17.2 ± 0.8 min; $P < 0.05$), VO_{2peak} and VCO_{2peak} compared to placebo, and also tended to increase pulmonary ventilation ($P = 0.07$) (124.8 ± 7.7 L/min versus 115.9 ± 7.7 L/min). Prior administration of the same dose daily for 4 weeks did not alter any of the variables measured (De Bock et al 2004). rhodiola has also been shown to exhibit an anti-inflammatory effect and protect muscle tissue during exercise in healthy untrained volunteers before and after exhausting exercise (Abidov et al 2004).

OTHER USES

Reward deficiency syndrome (RDS)

Reward deficiency syndrome (RDS), associated with low dopamine 2 (D2) receptors, may increase craving behaviour causing the individual to seek out substances that increase the release of dopamine. Researchers in this area have suggested that the addition of rhodiola, a known

catechol-O-methyl-transferase (COMT) inhibitor, may be a useful adjunct to the treatment of this condition. It is thought that during recovery or rehabilitation from alcohol or other psychoactive drugs (dopamine releasers), decreasing COMT activity should result in 'enhanced synaptic dopamine, thereby proliferating D2 receptors while reducing stress, increasing wellbeing, reducing craving behaviour and preventing relapse' (Blum et al 2007).

Cardiovascular disease prevention

In animal studies, rhodiola extract has demonstrated cardioprotective, antiarrhythmic and antioxidant effects (Lishmanov et al 1997, Maimeskulova & Maslov 2000, Maslov & Lishmanov 2007, Wing et al 2003). Further research is warranted to investigate whether these effects are clinically relevant in human populations at risk of cardiovascular disease.

Diabetes

In animal studies, rhodiola extract (200 mg/kg/day for 12 weeks) significantly decreased blood glucose and lipid peroxidation. It also increased the levels of reduced glutathione and the activities of glutathione reductase, glutathione S-transferase, glutathione peroxidase, catalase and superoxide dismutase in the liver. As increased oxidative stress has been shown to play an important role in the pathogenesis and long-term complications of diabetes mellitus, this herb warrants further investigation (Kim et al 2006).

DOSAGE RANGE

- Fluid extract (1:2): 20–40 mL/wk (Australian manufacturer recommendations).
- In clinical trials, extracts are often standardised to 3% rosavin and 1% salidroside (Perfumi & Mattioli 2007).
- Stress and fatigue: one-off acute dosing (equiv 9 mg/day–13.5 mg/day salidroside) (Shevtsov et al 2003); repeated low-dose treatment (eqiv. 4.5 mg/day of salidroside) (Darbinyan et al 2000).
- Depression and anxiety: rhodiola extract 340 mg/day (equiv 1500 mg dried root) (Bystritsky et al 2008, Darbinyan et al 2007).

Note: One study suggested improved results from taking rhodiola after breakfast rather than in divided doses after breakfast and lunch (Fintelmann & Gruenwald 2007). This may be due to diurnal variations in HPA and adrenal function.

ADVERSE REACTIONS

Serious adverse effects have not been reported in clinical trials; however, mild-to-moderate symptoms of dizziness and dry mouth have been noted (Bystritsky et al 2008).

SIGNIFICANT INTERACTIONS

As controlled studies are not available, interactions are currently speculative and based on evidence of pharmacological activity and animal studies.

Adriamycin

Rhodiola extract has been shown to reduce the liver dysfunction (suggested by a sharp increase in blood transaminase levels) associated with adriamycin in vivo without affecting the drug's antitumour effects (Udintsev et al 1992). Beneficial interaction possible under clinical supervision.

Cyclophosphamide

In animal tumour models (Ehrlich ascites tumour and Lewis lung carcinoma), the combination of rhodiola rosea extract with cyclophosphamide resulted in enhanced antitumour and antimetastatic activities and reduced drug-induced toxicity on bone marrow cells (Razina et al 2000, Udintsev & Schakhov 1991b). Beneficial interaction possible under clinical supervision.

Antidepressants

As recent in vitro data suggests an inhibition of MAO A by rhodiola extracts (van Diermen et al 2009), a theoretical interaction exists with MAOI antidepressants. The clinical significance of this and whether other antidepressants may be affected is as yet unclear. Observe.

CONTRAINDICATIONS AND PRECAUTIONS

While the administration of rhodiola may be beneficial in monopolar depression, use is not recommended for bipolar states.

Theoretically, the possibility of the herb exerting MAO inhibiting effects may require consumers to adhere to dietary restriction of tyramine-rich foods (e.g. some cheeses, pickled foods, chocolates, meats, beer, wine etc), as the interaction of tyramine with MAOIs can result in a significant elevation in blood pressure.

PREGNANCY USE

Safety in pregnancy and lactation has not been established.

PRACTICE POINTS/PATIENT COUNSELLING

- Rhodiola may exert an antidepressant effect via the inhibition of MAO A; inhibiting the sensitivity of glucocorticoid receptors to cortisol (induced by stress) or by facilitating neurotransmitter transport within the brain.
- Some studies suggest that extracts of rhodiola may increase stress resistance, improve fatigue and reduce anxiety.
- Multidose administration of rhodiola may influence the hypothalamic–pituitary–adrenal (HPA) axis, while single-dose applications are more useful in situations that require a rapid response to tension or to a stressful situation via the sympatho-adrenal-system (SAS).
- Animal studies show possible benefits in cardiovascular disease and diabetes, which may relate to its antioxidant effects.
- Limited trials in humans have failed to demonstrate significant benefits for enhancing physical performance.
- Many trials use rhodiola in combination with other herbs or nutrients making it difficult to ascertain the pharmacological and clinical effects of the individual herb.

PATIENTS' FAQs

What will this herb do for me?

Rhodiola may be of assistance in the treatment of stress-related conditions, in particular depression and fatigue.

When will it start to work?

Rhodiola exerts a stimulating effect within 30 min of administration that continues for approximately 4–6 h.

In mild-to-moderate depression, the benefits of rhodiola rosea extract SHR-5 (340 mg/day) or SHR-5 (680 mg/day) were noted at the end of a 6-week trial.

Are there any safety issues?

Mild-to-moderate symptoms of dizziness and dry mouth have been noted in clinical trials and patients taking MAOI antidepressants may need consideration until more is known about the mechanism of action of this herb. Safety in pregnancy and lactation has not been established.

Rosemary

HISTORICAL NOTE Since ancient times, rosemary has been used as a tonic and stimulant. The ancient Greeks used it to strengthen memory function and scholars wore garlands of rosemary during examinations in order to improve their memory and concentration (Blumenthal et al 2000). It is widely used as a food spice and as an antioxidant to preserve foods.

COMMON NAME
Rosemary

OTHER NAMES
Compass plant, compass weed, garden rosemary, old man, polar plant, *Rosmarini folium*

BOTANICAL NAME/FAMILY
Rosmarinus officinalis (family Labiatae or Lamiaceae)

PLANT PART USED
Fresh or dried leaf

CHEMICAL COMPONENTS
Phenolic acids and diterpenoid bitter substances, including carnosic acid and carnosol (Aruoma et al 1992, Bicchi et al 2000, Wei & Ho 2006), triterpenoid acids, flavonoids, tannins and volatile oils (0.5–2.5%) that consist of 1,8-cineole, 2-ethyl-4,5-dimethylphenol gamma-terpinene (Kabouche et al 2005), pinene, terpineol, camphor, camphene, borneol and bornyl acetate (Blumenthal et al 2000). Rosemary has also been found to contain high amounts of salicylates (Swain et al 1985).

MAIN ACTIONS

Antioxidant

Rosemary has strong antioxidant activity and is widely used to preserve food and cosmetics (Etter 2004). Rosemary leaf extract has been shown to enhance superoxide dismutase activity (Kim et al 1995) and to have an effect stronger than vitamin E in scavenging oxygen radicals (Zhao et al 1989). It is suggested that carnosol and carnosic acid account for over 90% of its antioxidant properties (Aruoma et al 1992, 1996). Carnosic acid has been shown to have a photoprotective action on human dermal fibroblasts exposed to UVA light in vitro (Offord et al 2002) and rosemary extract inhibits oxidative alterations to skin surface lipids, both in vitro and in vivo (Calabrese et al 2000), as well as enhancing cell-mediated immunity in rats under oxidative stress (Babu et al 1999). In a study of 150 patients with bronchitis exposed to essential oils of rosemary, basil, fir and eucalyptus, an antioxidant effect was observed (Siurin 1997).

Antibacterial

Rosemary extract demonstrates in vitro antibacterial activity against a variety of bacteria (Del Campo et al 2000, Erdogrul 2002, Ouattara et al 1997), including *Helicobacter pylori* (Mahady et al 2005), *Staphylococcus aureus* (Oluwatuyi et al 2004), *Klebsiella pneumoniae* and *Pseudomonas aeruginosa* (Kabouche et al 2005). Topical application of rosemary essential oil preparations has been found to have antifungal activity (Ouraini et al 2005, Steinmetz et al 1988, Suleimanova et al 1995) and to inhibit the growth and aflatoxin production of *Aspergillus* spp at concentrations between 0.2% and 1% (Tantaoui-Elaraki & Beraoud 1994). Carnosol has been found to have anti-HIV activity (Aruoma et al 1996) and carnosic acid has also been shown to have an inhibitory effect on HIV-1 protease in cell-free assays (Paris et al 1993). Rosemary extract has some antiviral activity against HSV (Vijayan et al 2004). Powdered rosemary leaves are said to be effective as a natural flea and tick repellent and rosemary essential oil has been found to be ovicidal and repellent towards mosquito (Prajapati et al 2005).

Anti-inflammatory

In vitro studies have found that rosemary extracts inhibited inflammatory-induced peroxynitrite radical and nitrite production (Chan et al 1995, Choi et al 2002) and that carnosol suppresses NO production (Lo et al 2002). Rosmarinic acid has been found to increase the production of PGE_2, reduce the production of leukotriene B_4 in human polymorphonuclear leucocytes, and inhibit the complement system (al-Sereiti et al 1999).

Hepatoprotective

The hepatoprotective properties of rosemary extract are attributed to its antioxidant properties and improving detoxification systems dependent on glutathione S-transferase (Sotelo-Felix et al 2002). Rosemary extract has been shown to reduce thioacetamide-induced cirrhosis (Galisteo et al 2000) and azathioprine-induced toxicity in rats (Amin & Hamza 2005), as well as partially prevent carbon tetrachloride-induced liver damage in both rats (Sotelo-Felix et al 2002) and mice (Fahim et al 1999, Sotelo-Felix et al 2002).

Chemoprotection and antimutagenic effects

In vivo studies suggest that rosemary extract may reduce the effects of carcinogenic or toxic agents on many cell lines, including rat mammary gland (Amagase et al 1996, Singletary et al 1996), mouse liver and stomach (Singletary & Rokusek 1997), bone marrow (Fahim et al 1999) and skin (Huang et al 1994).

An in vitro study on human bronchial cells found that rosemary extract and its constituents, carnosol and carnosic acid, may have chemoprotective activity by decreasing carcinogen activation via inhibition of the enzyme cytochrome P450 (CYP1A1) and increasing carcinogen detoxification by induction of phase II enzymes (Offord et al 1995). Carnosol has been found to also restrict the invasive ability of mouse melanoma cells in vitro by reducing MMP-9 expression and activity (Huang et al 2005).

Increases oestrogen metabolism

Feeding female mice a 2% rosemary diet enhanced the liver microsomal metabolism of endogenous oestrogens (Zhu et al 1998), thereby reducing oestrogen levels.

OTHER ACTIONS

Carnosic acid and carnosol, which are major components of rosemary, have been found to markedly enhance synthesis of nerve growth factor in vitro (Kosaka & Yokoi 2003). Rosemary has been also demonstrated to have significant antithrombotic activity in vitro and in vivo, possibly through a direct inhibitory effect on platelets (Yamamoto et al 2005). Rosemary essential oil and its constituent monoterpenes, such as borneol, have been found to inhibit bone resorption in the rat (Muhlbauer et al 2003). Aqueous and ethanol extracts of rosemary have been found to produce significant antinociceptive activity and diminish morphine withdrawal syndrome in rats (Hosseinzadeh & Nourbakhsh 2003).

Rosemary extract may delay and inhibit tumour formation in women with breast cancer (Abascal & Yarnell 2001) and prevent mesangial cell proliferation in cultured murine mesangial cells (Makino et al 2000).

When used topically, rosemary essential oil is said to stimulate the skin and increase blood circulation (Blumenthal et al 2000).

CLINICAL USE

Increased mental concentration

One of the main traditional uses of rosemary oil is to increase mental concentration and memory. This is supported by a RCT of 140 subjects that found that rosemary produced a significant enhancement

of performance for overall quality of memory and secondary memory factors, with an impairment of speed of memory compared with controls (Moss et al 2003). Further support comes from an observational study in 40 adults where 3 minutes' exposure to rosemary essential oil was seen to decrease frontal alpha and beta power, suggesting increased alertness. Subjects felt more relaxed and alert, had lower anxiety scores and were faster, but not more accurate, at completing maths computations (Diego et al 1998). A small, case series of 10 subjects also found that rosemary essential oil had positive effects on mood concentration and memory (Svoboda et al 2002). Moss et al 2003 demonstrated significantly enhanced overall memory quality but impaired memory speed using rosemary essential oil placed on diffuser pads in an aroma stream placed in test cubicles and switched on for 5 min prior to testing (n = 140, divided into three groups: lavender, rosemary and control).

Alopecia

The traditional use of rosemary to stimulate hair growth is supported by a 7-month, randomised, double-blind study of 86 patients that found rubbing oils (thyme, rosemary, lavender and cedarwood) into the scalp helped with alopecia for 44% of patients versus 15% of controls (Hay et al 1998). Although promising, the role of rosemary as a standalone substance in achieving these results is unclear.

Antispasmodic

Rosemary is widely acknowledged to be a carminative and is used internally as an antispasmodic for mild cramp-like gastrointestinal and biliary upsets, as well as for tension headache, renal colic and dysmenorrhoea (Blumenthal et al 2000). It is also used to relax bronchial smooth muscle in the treatment of asthma (al-Sereiti et al 1999), but controlled studies are unavailable to determine clinical efficacy.

Chemoprotective and adjunct in cancer therapy

Rosemary was used topically to treat cancer in ancient Greece and South America. Although controlled trials are yet to be conducted, it has been suggested that rosemary may delay and inhibit tumour formation in women with breast cancer (Abascal & Yarnell 2001) and that it has potential as a preventive agent or as an adjunct in cancer therapy. An in vitro study in human breast cancer cells found that rosemary extract increased the intracellular accumulation of commonly used chemotherapeutic agents, including doxorubicin and vinblastine via inhibition of P-glycoprotein, thereby overcoming multidrug resistance in tumour cells (Plouzek et al 1999). Clinical studies are required to determine whether the effect is significant.

OTHER USES

When applied topically, rosemary oil may stimulate the blood supply and act as supportive therapy for rheumatic conditions and circulatory problems (Blumenthal et al 2000). Topically, rosemary has also been used for wound healing, as an insect repellent and to treat toothache and eczema. Rosemary extract cream preparations have been shown to protect against sodium lauryl sulfate-induced irritant contact dermatitis (Fuchs et al 2005).

In a small, uncontrolled, prospective pilot study of eight women, rosemary in combination with 11 other botanical extracts was found to relieve menopausal symptoms (Smolinski et al 2005).

DOSAGE RANGE

- Infusion of dried leaf: 2–4 g three times daily.
- Fluid extract (45%): 1–4 mL three times daily.
- Topical preparations containing 6–10% essential oil can be applied directly to skin. Often a carrier oil, such as almond oil, is used as a vehicle for the essential oil.
- Bath additive: 10 drops essential oil added to bath.

ADVERSE REACTIONS

Rosemary is generally recognised as safe for human consumption in quantities used as food. Consuming large amounts of rosemary may cause stomach and intestinal irritation, as well as seizures, owing to the high content of highly reactive monoterpene ketones, such as camphor (Burkhard et al 1999). Topically, rosemary is not considered to be highly allergenic; however, allergic contact dermatitis from rosemary has been reported (Fernandez et al 1997, Hjorther et al 1997, Inui & Katayama 2005), as has asthma from repeated occupational exposure (Lemiere et al 1996). Rosemary essential oil should be diluted before topical application to minimise irritation.

SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

Iron

Rosemary extracts are widely used as an antioxidant to preserve foods; however, the phenolic-rich extracts may reduce the uptake of dietary iron (Samman et al 2001). Separate doses by 2 h.

Anticoagulants

Increased bruising and bleeding theoretically possible — use caution.

Drugs dependent on P-glycoprotein transport

Theoretically, increased drug uptake can occur with those drugs dependent on P-glycoprotein transport. The clinical significance of this finding remains to be tested, although it has been suggested that this activity may be used to enhance the effects of chemotherapeutic agents (Plouzek et al 1999).

CONTRAINDICATIONS AND PRECAUTIONS

None known.

PREGNANCY USE

Rosemary has been shown to have an anti-implantation effect in rats, without interfering with normal fetal development postimplantation (Lemonica et al 1996). It is not recommended in pregnancy in doses higher than the usual dietary intake levels until safety is established or only under professional supervision.

PRACTICE POINTS/PATIENT COUNSELLING

- Rosemary is widely used as a food seasoning and preservative.
- Rosemary extract exhibits antioxidant, antibacterial, anti-inflammatory, hepatoprotective and chemoprotective activities in various in vitro and experimental models.
- Rosemary oil is widely used to assist in concentration and memory and to stimulate blood flow.
- Traditionally, it has been used to relieve stomach, gall bladder and menstrual cramps, but its internal use has not yet been significantly investigated in controlled studies.
- Rosemary is generally safe when the leaves are consumed in dietary amounts, although excessive intake may cause stomach irritation and seizures in susceptible people.

S-Adenosyl-L-methionine (SAMe)

HISTORICAL NOTE SAMe was first discovered in Italy in 1952. About 20 years later, a stable salt was commercially manufactured and produced for injectable use. At first, it was investigated as a treatment for schizophrenia, for which it proved inappropriate; however, successful trials in depressed patients began in the 1970s and it was inadvertently found to improve symptoms of arthritis. Since then, numerous studies have been undertaken to examine the role of SAMe in treating depression, osteoarthritis and liver pathology. To date, more than 75 clinical trials have been conducted using SAMe as a therapeutic agent, involving over 23,000 people.

BACKGROUND AND RELEVANT PHARMACOKINETICS

SAMe is synthesised in the cytosol of every cell, with the liver being the major site of biosynthesis and degradation. Up to half the daily methionine is converted to SAMe in the liver, where it is metabolised to *S*-adenosylhomocysteine and then homocysteine (Hcy). Being a central part of the one-carbon metabolism cycle, SAMe is intrinsically linked with the other methyl donors such as folate and B12.

SAMe naturally exists as diastereoisomers and it is presently unclear whether both the R and S forms are biologically active in humans. Evidence from a rat model suggests that they are equipotent (Dunne et al 1998). Oral doses achieve peak plasma concentrations within 3–5 h after ingestion of an enteric-coated tablet (400–1000 mg). Enteric coating of SAMe supplements is essential to ensure product stability and potency. The half-life is reported to be 100 min, and excretion occurs via both urine and faeces (Najm et al 2004).

MAIN ACTIONS

SAMe is involved in myriad biochemical processes and metabolic pathways, chiefly as a methyl donor. It is involved in the synthesis of many important biochemicals, such as creatine, melatonin, glutathione, RNA and DNA, phospholipids, proteins, adrenaline and amino acids L-cysteine and taurine. SAMe is closely linked with the metabolism of folate and vitamin B12.

This review only discusses those actions that have been confirmed clinically.

Antidepressant activity

SAMe supplementation produces a clinically significant antidepressant activity that has been demonstrated in numerous trials.

The mode of antidepressant action is unknown, but is likely to involve several mechanisms. As a methyl donor, SAMe plays a role in the metabolism of various CNS neurotransmitters that play an integral part in synaptic transmission and behaviour, such as noradrenaline, dopamine and serotonin (Bottiglieri 1996). Supplementation with SAMe in depressed patients raises serotonin, dopamine and phosphatidylserine and improves neurotransmitter binding to receptor sites, resulting in increased activity (Pizzorno & Murray 2006). More recent evidence suggests that the dopaminergic activity is most prominent. One human study confirmed that 7 days of supplemental SAMe

(400 mg/day) decreased the exaggerated plasma noradrenaline levels found in depressed patients (Sherer et al 1986). It is also involved in the formation of phosphatidylcholine, a major component of cell membranes and neurotransmission (Carney et al 1987).

Interestingly, significantly low levels of SAMe in cerebrospinal fluid have been observed in severely depressed patients compared with controls (Bottiglieri et al 1990); however, the significance of this finding is unknown.

Anti-inflammatory

A substantial body of evidence has identified clinically significant anti-inflammatory activity for SAMe with comparative trials showing it to be as effective as standard NSAIDs.

Although the mechanism of action remains unclear, it does not appear to be mediated by PG. SAMe stimulates the synthesis of proteoglycans by articular chondrocytes and exerts a chondroprotective effect, according to in vitro research and tests with experimental animals (Barcelo et al 1987, Clayton 2007, Harmand et al 1987). In vitro studies using cultured rabbit synovial cells has found that SAMe reduces TNF-alpha and fibronectin RNA expression (Gutierrez et al 1997). Clinical responses suggest a concomitant analgesic property; however, once again, the mechanism for this remains unknown (Clayton 2007).

Hepatoprotective effects

SAMe indirectly reduces oxidative stress in the liver by serving as a precursor for glutathione. Glutathione is particularly important for reducing the toxic effects of free radical molecules generated by various substances, including alcohol. SAMe also acts as the main methylating agent in the liver. Research with people with alcoholic and non-alcoholic liver diseases confirms that SAMe supplementation significantly increases hepatic glutathione levels (Vendemiale et al 1989). Additionally, in vitro research has identified antifibrotic activity and, recently, enhanced production of IL-6, a key anti-inflammatory cytokine in the liver that assists regeneration and downregulation of TNF (Arteel et al 2003, Casini et al 1989, Song et al 2004). Research using animal models demonstrates that SAMe is a natural growth regulator in hepatocytes and is anti-apoptotic in healthy liver cells, but pro-apoptotic in hepatic carcinoma cells (Lu & Mato 2005).

OTHER ACTIONS

Prolactin and thyroid stimulating hormone (TSH) effects

A double-blind, placebo-controlled study involving 20 subjects with depression identified a significant reduction in prolactin concentrations following 14 days of SAMe treatment (Thomas et al 1987). The results of a study conducted in 1990, however, suggest that the effects on these hormones may be gender specific, with women demonstrating an augmenting response of TSH and no effect on prolactin levels, whereas release of both TSH and prolactin was inhibited in male subjects (Fava et al 1990). If SAMe does exert dopaminergic effects, as presently suspected, then it should also be taken into consideration that dopamine naturally inhibits both TSH and prolactin secretion in humans.

Antioxidant

SAMe exhibited direct antioxidant activity in vitro (Caro & Cederbaum 2004).

CLINICAL USE

Although SAMe is administered as an oral supplement in Australia, it is also used in injectable dose forms in Europe. This discussion will mainly focus on oral use.

Osteoarthritis (OA)

A 2004 meta-analysis of 11 RCTs involving almost 1500 patients, comparing SAMe with either placebo or NSAIDs, concluded that SAMe is as effective as NSAIDs in reducing pain and improving functional limitation in patients with OA of the knee. In addition, SAMe-treated patients were 58% less likely to experience adverse effects than those treated with NSAIDs (Soeken et al 2002).

The longest clinical trial to date was conducted over 2 years and found that a loading dose of oral SAMe 600 mg/day taken over the first 2 weeks, followed by a maintenance dose of 400 mg, produced an improvement in symptoms within the first month and no serious adverse effects (Konig 1987).

Comparative studies

Comparative studies in humans have found that oral SAMe (1200 mg) produces similar symptom-relieving effects as piroxicam (20 mg), ibuprofen (1200 mg), indomethacin (150 mg) or naproxen (750 mg) (Caruso & Pietrogrande 1987, Glorioso et al 1985, Maccagno et al 1987, Muller-Fassbender 1987, Vetter 1987).

A 16-week randomised, double-blind, crossover study of 61 individuals with OA of the knee compared the efficacy of SAMe (1200 mg/day) with celecoxib (200 mg/day). At this dose, SAMe was as effective as celecoxib in providing significant symptom relief; however, it had a slower onset of action, requiring 1 month of continuous use before benefits were felt (Najm et al 2004). It has been suggested that the antidepressant activity may be a confounding factor in these trials; however, another trial (Clayton 2007) was unable to detect an antidepressant effect for SAMe.

Depression

Several reviews and at least two meta-analyses have examined the available evidence for SAMe for trials completed prior to 1994 and have concluded that SAMe is superior to placebo, is as effective as standard tricyclic antidepressants and is better tolerated in the treatment of depressive disorders (Bressa 1994, Fetrow & Avila 2001).

The review conducted in 2005 assessed results from 11 studies and concluded that the evidence for SAMe was positive in depression, but currently hampered by the short duration of trials and

questions over the oral bioavailability of the products used (Williams et al 2005). Advantages consistently noted by reviewers include the faster onset of action observed with SAMe-treated patients (10 days) compared to treatment with SSRIs (21 days) and the lack of many side effects that plague the pharmaceutical antidepressants (Mischoulon & Fava 2002).

A trial implementing 800–1600 mg/day SAMe as an adjunctive agent in 30 treatment-resistant patients over a 6-week trial revealed a staggering 50% response rate, with 43% of the sample experiencing remission of symptoms (Alpert et al 2004). Positive results such as these warrant further investigation of SAMe in this adjunctive role with more stringent trial designs. Due to case reports of agitation and mania in bipolar patients taking this nutraceutical, SAMe should not be used in the depressive phase of this condition, until more research is conducted (Andreescu et al 2008, Bogarapu et al 2008).

Parkinson's disease and depression

High-dose SAMe (800–3600 mg/day) treatment was investigated in a pilot study involving 11 depressed patients with Parkinson's disease, all of whom had been previously treated with other antidepressant agents and had no significant benefit or intolerable side effects. After 10 weeks, 10 patients had at least a 50% improvement on the Hamilton Depression Scale, with only one patient showing no improvement. The mean score before treatment was 27.09 and was 9.55 after SAMe treatment (Di Rocco et al 2000).

Fibromyalgia

Four double-blind trials have investigated the effects of SAMe in fibromyalgia, with all reporting positive findings (Jacobsen et al 1991, Tavoni et al 1987, 1998, Volkmann et al 1997) such as reduced number of trigger points and areas of pain, improved mood and reduced fatigue (Sarac & Gur 2006). Two studies used injectable SAMe (200 mg daily).

The largest study involved 44 patients with primary fibromyalgia and found that during week 5, the group receiving SAMe (800 mg/day) experienced improvements in clinical disease activity, pain, fatigue, morning stiffness and one measurement of mood. Although encouraging, not all parameters were improved beyond placebo, such as tender point score and isokinetic muscle strength (Jacobsen et al 1991).

These results should not be surprising, given that one-third of all fibromyalgia patients are reported to suffer from depression and a meta-analysis of the effectiveness of antidepressants (including SAMe) in fibromyalgia deemed them a successful treatment strategy (O'Malley et al 2000). It concluded that tricyclic antidepressants, SSRIs and SAMe all improved sleep, fatigue, pain and wellbeing, but not necessarily trigger points.

Schizophrenia

Eighteen patients with chronic schizophrenia were randomly assigned to receive either SAMe (800 mg) or placebo for 8 weeks in a double-blind study. Active treatment resulted in some reduction in aggressive behaviour and in improved quality of life. This is a notable finding, as improvement in quality of life is considered a critical outcome measure in the management of schizophrenic illness. Interestingly, female patients also showed improvement of depressive symptoms and clinical improvement did not correlate with serum SAMe levels. Two patients in the active group exhibited some exacerbation of irritability; however, it is unclear whether the effect was due to SAMe administration or whether it was an unrelated deterioration, as relapse is common in patients with chronic schizophrenia. Further studies using larger samples are required to test these initial findings.

Liver cirrhosis

It is now generally accepted that in alcoholic patients with advanced liver cirrhosis, hepatic SAMe concentration is greatly decreased through alcohol exposure (Cave et al 2007, Kharbanda 2007, Lieber 2002). While transient SAMe depletion is necessary for the liver to regenerate, chronic hepatic SAMe depletion may lead to malignant transformation (Lu & Mato 2005, 2008). In the interim-depressed hepatic SAMe, especially together with a reduced SAM:SAH (S-adeonsylhomocysteine) ratio, results in impaired transmethylation, producing increased fat deposition, apoptosis and accumulation of damaged proteins — all characteristic features of liver injury (Cave et al 2007, Kharbanda 2007). Primate studies have found that decreased hepatic SAMe concentrations and associated liver lesions, including mitochondrial injury, can be corrected with SAMe supplementation (Lieber et al 1990), with reduced markers of lipid peroxidation, histological evidence of liver injury and maintained mitochondrial glutathione (GSH) (Cave et al 2007).

A 2006 Cochrane review of SAMe in alcoholic liver disease analysed results from nine randomised clinical trials that included a heterogeneous sample of 434 patients (Rambaldi & Gluud 2006). The methodological quality was considered low; however, eight of the trials were placebo controlled. As a result, the analysis was based mainly on one trial that found no significant effects of SAMe on all-cause mortality, liver-related mortality, liver transplantation or complications. The authors concluded that based on such limited evidence, more long-term, high-quality randomised trials of SAMe for these patients are required before SAMe may be recommended for clinical practice.

Non-alcoholic fatty liver disease (NAFLD) or non-alcoholic steatohepatitis (NASH)

Human studies have demonstrated that patients with liver disease have an impaired ability to convert methionine to SAMe and decreased plasma and hepatic GSH levels (Cave et al 2007. SAMe has been shown to improve GSH in patients with liver disease after 6 months of oral therapy. Of particular interest is recent evidence from animal studies which suggest that SAMe depletion in the early stages of NASH may be a key point of disease progression into NAFLD (Lu & Mato

2008, Wortham et al 2008). Clinical trials have demonstrated benefit from SAMe therapy in various forms of liver disease, including alcoholic cirrhosis and intrahepatic cholestasis of pregnancy. SAMe supplementation has also demonstrated attenuation of inflammation and liver injury in a nutritional deficiency model of steatohepatitis and clinical trials in NASH patients are currently under way (Cave et al 2007). In lieu of more solid evidence to support SAMe as a therapeutic agent in NASH and NAFLD, the preferred current treatment is betaine, which by virtue corrects SAMe depletion (Kharbanda 2007, Kwon et al 2008).

Hepatic cancer

Due to its role in the regulation of growth and apoptosis of hepatocytes, SAMe is being investigated as a possible preventative or treatment agent in hepatocellular carcinoma (Lu & Mato 2005, 2008).

OTHER USES

SAMe is used to reduce pain in migraine headache because analgesic activity was reported at a dose of 400–800 mg/day in a group of migraine sufferers (Gatto et al 1986). It is also used in AIDS-related myelopathy and coronary artery disease, as these conditions have been associated with depleted SAMe levels. Supplementation has also been prescribed in cases of general fatigue, poor digestion, allergies and elevated homocysteine levels.

DOSAGE RANGE

Based on clinical studies

- Depression: 400–1600 mg/day in divided doses. Usually 1200–1600 mg/day. Sometimes it is started as 200 mg twice daily, increased on day 2 to 400 mg twice daily and then increased again to 400 mg three times daily on day 10, until reaching the full therapeutic dose of 400 mg four times daily by day 20, if necessary (Pizzorno & Murray 2006).
- Osteoarthritis: 1200 mg/day in divided doses, taken as above, with a reduced dose of 400 mg/day used as a maintenance dose once a response occurs.
- Fibromyalgia: 600–800 mg/day in divided doses.
- Liver diseases: 400–1200 mg/day in divided doses, although larger doses have been used.
- Parkinson's disease: 800–3600 mg/day in divided doses.
- Migraine: 400–800 mg/day in divided doses.
  - Reducing aggression in schizophrenia: 800 mg/day (only under supervision).

ADVERSE REACTIONS

Orally, SAMe is generally well tolerated. Mild gastrointestinal discomfort is the most common side effect reported in clinical studies, although anxiety, headache, urinary frequency, dizziness, nervousness, sweating and pruritis have also been reported. It has been reported that side effects are more likely with higher doses and may be minimised by consuming SAMe before food.

SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

Tricyclic antidepressants and other serotonergic agents

Theoretically, co-administration may result in an increased risk of serotonin syndrome. However, one experimental study found that brain SAMe levels were significantly reduced after chronic treatment with imipramine (Taylor & Randall 1975) — use this combination with caution.

Hepatotoxic drugs

SAMe may reduce hepatic injury caused by such agents as paracetamol, alcohol and oestrogens — potentially beneficial interaction.

L-Dopa

SAMe methylates levodopa, which could theoretically reduce the effectiveness of levodopa given for Parkinson's disease; however, the effect has not been observed clinically — observe patients.

Thyroxine

Caution and monitoring may be warranted.

Betaine

In studies supplementing mice with betaine, significant increases in SAMe were observed with a three-fold elevation of the activity of methionine adenosyltransferase — observe.

CONTRAINDICATIONS AND PRECAUTIONS

SAMe should be avoided in people with bipolar disorder and used with caution by people with schizophrenia or schizoaffective disorder, or Parkinson's disease (Guidotti 2007, Pizzorno & Murray 2006).

PREGNANCY USE

SAMe has been used intravenously in the last trimester of pregnancy with no adverse effects to mother or fetus. However, safety has not yet been conclusively established for either injectable or oral dose forms and possible effects on prolactin levels need to be considered.

PATIENTS' FAQs

What will this supplement do for me?

SAMe has anti-inflammatory, analgesic, antidepressant and protective effects on the liver. It effectively reduces pain and inflammation in OA and elevates mood in depression. In fibromyalgia, SAMe reduces pain, fatigue and morning stiffness and may also reduce pain in migraine headache.

When will it start to work?

Beneficial effects are usually seen within 4–5 weeks for OA, whereas antidepressant effects are experienced within 1 week. Benefits in fibromyalgia can take up to 6 weeks to establish.

Are there any safety issues?

SAMe should be used with caution by people with bipolar disorder, schizophrenia or schizoaffective

disorder, Parkinson's disease or taking antidepressant medicines. Monitoring of homocysteine levels may be required with long-term supplementation.

PRACTICE POINTS/PATIENT COUNSELLING

- SAMe is involved in myriad biochemical reactions within the body and found within every cell.
- Clinically, it has anti-inflammatory, analgesic, antidepressant and hepatoprotective activities.
- A 2002 meta-analysis concluded that SAMe is as effective as NSAIDs in reducing pain and improving functional limitation in patients with OA without the adverse effects associated with NSAIDs. A recent study has found that it is as effective as celecoxib for providing symptom relief; however, SAMe has a slower onset of action.
- Clinical trials have also shown it to be a safe and effective treatment for depression, comparable with tricyclic antidepressant drugs, yet with a faster onset of action.
- SAMe also appears to be useful in fibromyalgia, and possibly migraine headache. Its usefulness in alcoholic liver disease is unclear. Other uses include treatment of general fatigue, elevated homocysteine levels, allergies and poor digestion.

Sage

HISTORICAL NOTE The *Salvia* genus is one of the largest groups of the Lamiaceae family with over 700 species spread throughout the world (Nickavar et al 2005). Sage has been used since ancient times as an antiseptic, astringent, tonic, carminative, antispasmodic, anti-inflammatory and to reduce sweating agent in various traditional medicine systems. The name 'Salvia' derives from the Latin salvere (to be saved) (Blumenthal et al 2000). Sage oil is used as a culinary spice and as a fragrance in soaps and perfumes. The fragrance is said to suppress the odour of fish.

OTHER NAMES

Broad-leafed sage, common sage, dalmatian sage, garden sage, meadow sage, Spanish sage, true sage

BOTANICAL NAME/FAMILY

Salvia officinalis, *Salvia lavandulaefolia*, *Salvia hypoleuca* Benth (family Labiatae or Lamiaceae).

PLANT PART USED

Leaf

CHEMICAL COMPONENTS

The exact chemical constituents depend on geographic and climatic conditions as well as harvesting conditions, distillation method and the part of the plant used (Nickavar et al 2005). The leaves contain up to 2.5% essential oil, which contains thujone, cineol and camphor, as well as humulene, pinene, camphene, limonene, carnosol and rosmarinic acid. In addition, the leaves contain catechin-type tannins, diterpene bitter principles, triterpenes, steroids, flavones, and flavonoid glycosides, together with polysaccharides. Sage is a rich source of beta-carotene, vitamins C and B-complex (Fisher & Painter 1996). The flowering parts of *S. hypoleuca* contain bicyclogermacrene, (E)-beta-caryophyllene, viridifloral, spathulenol, beta-pinene and delta-pinene. Pharmacopoeial grade sage leaf must contain not less than 1.5% thujone-rich volatile oil (Blumenthal et al 2000).

MAIN ACTIONS

Antimicrobial

Sage is reported to have antimicrobial activity attributed to the thujone, thymol and eugenol contents of the volatile oil (Shapiro et al 1994), as well as its rosmarinic acid content (Petersen & Simmonds 2003). The phenolic acids, salvins and monomethyl ethers have also been attributed with antimicrobial activity. Overall, activity has been reported in vitro against *Staphylococcus aureus*, *Escherichia coli*, *Salmonella* spp, *Shigella sonnei*, *Klebsiella ozanae*, *Bacillus subtilis* and various fungi, including *Candida albicans* (Newell et al 1996). Phenolic extracts have also shown antibacterial activity against *Enterococcus* (Feres et al 2005). Sage had some in vitro antimicrobial effects on saliva samples from periodontally healthy and diseased subjects, although it had less activity than clove or propolis (Feres et al 2005). Sage essential oil has been shown to have effective inhibitory activity against microorganisms, such as *Klebsiella* spp, *Enterobacter* spp, *E. coli*, *Proteus mirabilis* and *Morganella morganii*, isolated from urinary tract infection (Santos Pereira et al 2004). There are also reports that sage may also be fungistatic and virustatic (Eidi et al 2005).

Antioxidant

Sage extracts have been shown to have strong antioxidant activity (Matsingou et al 2003, Pizzale et al 2002), with labiatic acid and carnosic acid reported to be the active compounds (Perry et al 2003). According to in vivo studies with animal models, ingestion of sage infusion improves the liver's antioxidant status (Lima et al 2005) and protects against azathioprine-induced toxicity (Amin & Hamza 2005). However, sage essential oil did not show protective effects against toxicity from an oxidative compound in isolated rat hepatocytes (Lima et al 2004).

Astringent

The high tannin content of sage supports its reported astringent activity.

Antispasmodic
Sage oil has antispasmodic effects in laboratory animals (Newell et al 1996) and this is likely due to the irritating effects of the volatile oil. There is some evidence that sage oil may also exert a centrally mediated antisecretory action.

Anxiolytic
Rosmarinic acid, which is a component of sage essential oil, produces an anxiolytic-like effect without exerting locomotor alterations or DNA damage in the brain tissue of rats (Pereira et al 2005). According to in vitro tests, compounds in the methanolic extract have an affinity for human brain benzodiazepine receptors (Kavvadias et al 2003).

Anticholinesterase
In vitro and in vivo studies suggest that sage essential oil and some individual monoterpenoid constituents inhibit acetylcholinesterase activity (Perry et al 2003). An extract of the sage leaf exhibited dose-dependent, in vitro inhibition of acetylcholinesterase (Kennedy & Scholey 2006).

OTHER ACTIONS
The water-soluble polysaccharide complex from sage has demonstrated immunomodulatory activity (Capek & Hribalova 2004) and the terpenoid fractions have shown antimutagenic properties in vivo (Vujosevic & Blagojevic 2004). In vitro and in vivo studies indicate that sage essential oil and some individual monoterpenoid constituents demonstrate antioxidant, anti-inflammatory and oestrogenic effects (Perry et al 2003).

Sage extract has been found to also significantly decrease serum glucose in diabetic rats without affecting insulin release, suggesting a possible role in diabetes (Eidi et al 2005). It has been suggested that extracts of sage containing carnosic acid may act as a new class of lipid absorption inhibitor. A methanolic extract of sage has also shown significant inhibitory effect on serum triglyceride elevation in olive oil-loaded mice, and inhibitory activity against pancreatic lipase, mainly because of the carnosic acid content. Carnosic acid was also found to reduce the weight gain and accumulation of epididymal fat in high-fat diet-fed mice after 14 days (Ninomiya et al 2004).

CLINICAL USE
Although sage has not been the subject of many clinical studies, many of its constituents demonstrate significant pharmacological effects, providing a theoretical basis for some of its uses.

Reduces secretions
Sage has been traditionally used to treat excessive perspiration and salivation, dysmenorrhoea, diarrhoea, galactorrhoea and sweats associated with menopause and to cease lactation (Fisher & Painter 1996). An open study of 80 patients confirmed that it can reduce perspiration (Blumenthal et al 2000). The high tannin content of the herb provides a theoretical basis for its use.

Dyspepsia and lack of appetite
Sage's reported antispasmodic action and bitter constituents support its use in treating loss of appetite, gastritis, flatulence, bloating and dyspepsia. These uses await support from clinical research.

Inflammation of mucous membranes
Topically, sage is used as a gargle for laryngitis, pharyngitis, stomatitis, gingivitis, glossitis, minor oral injuries and inflammation of the nasal mucosa (Blumenthal et al 2000). These uses can be based on the pharmacological activity of its chemical components. In an open-label, single-blind RCT of 420 patients, the non-steroidal anti-inflammatory drug benzydamine hydrochloride was found to be more effective than sage in relieving postoperative pain when used as a mouthwash after tonsillectomy in children and adults (Lalicevic & Djordjevic 2004).

Sage has been found to have less antitussive effects than codeine, but a significantly higher or similar effect to dropropizine (Nosalova et al 2005). A small double-blind study has suggested that use of an essential oil spray or gargle formulation that includes sage may help relieve snoring (Prichard 2004).

Pharyngitis
A randomised, double-blind, parallel group study compared the efficacy and tolerability of spray (containing a *Salvia officinalis* fluid extract) against placebo in the treatment of patients with acute viral pharyngitis (Hubbert et al 2006). A total of 286 patients with subjective and objective evidences of pharyngitis were randomised to receive placebo or treatment for 3 days, including one baseline visit and one final visit. The 15% spray containing 140 microlitre sage extract per dose was statistically significantly superior to placebo in reducing the throat pain intensity score. Symptomatic relief occurred within the first 2 h after first administration and only minor side effects such as dry pharynx or burning of mild intensity were seen.

Memory enhancement
Since ancient times, sage has been used to enhance memory and treat dementia. More recently, cholinergic activities have been demonstrated in vitro and in vivo, suggesting that it may be useful in treating Alzheimer's disease (Perry et al 2001). A randomised placebo-controlled study undertaken at three centres assessed the effects of sage extract (60 drops/day) in 42 subjects with mild-to-moderate Alzheimer's disease (Akhondzadeh et al 2003). Initially, subjects had a score of 12 or less on the cognitive subscale of Alzheimer's Disease Assessment Scale (ADAS-cog) and two or less on the Clinical Dementia Rating (CDR). At 4 months, sage extract produced a significantly better outcome on cognitive functions than placebo in both test scales and was well tolerated.

In 2003, two placebo-controlled, double-blind, crossover studies involving 44 healthy young adults investigated the effects of different strengths of standardised essential oil of *S. lavandulaefolia* on memory (Tildesley et al 2003). Both studies found

that a 50-microlitre dose of *Salvia* essential oil significantly improved immediate word recall and was able to modulate cognition. In another placebo-controlled, double-blind, crossover study involving 24 subjects, Spanish sage (*S. lavandulaefolia*) essential oil was found to enhance cognitive performance and mood in healthy young adults (Tildesley et al 2005).

In 2006, results of a double-blind, placebo-controlled, crossover study were published involving 30 healthy participants who received a series of different treatments on each visit to the research laboratory (placebo, 300, 600 mg dried sage leaf) (Kennedy & Scholey 2006). The results confirm previous observations of the cholinesterase inhibiting properties of *S. officinalis*, and improved mood and cognitive performance following the administration of single doses to healthy young participants.

Menopausal symptoms

Sage is commonly used by modern herbalists in prescriptions for menopause in order to treat hot flushes, night sweats, and for its oestrogenic effect. As yet, there is no clinical evidence available to confirm effectiveness for these indications (Blumenthal et al 2000).

OTHER USES

As an inhalant, sage is used for asthma. In foods, it is used as a culinary spice. In manufacturing, sage is used as a fragrance component in soaps and cosmetics. Topically, sage is used to treat herpes labialis, laryngitis, pharyngitis, stomatitis, gingivitis, glossitis, minor oral injuries and inflammation of the nasal mucosa.

DOSAGE RANGE

Internal use

- Infusion of dried herb: 1–4 g three times daily.
- Tincture (1:1): 1–4 mL three times daily.
- Essential oil: 2–3 drops in 100 mL water several times daily.
- Gargle or rinse (use warm infusion): 2.5 g cut leaf in 100 mL water; or 2–3 drops essential oil in 100 mL water; or use 5 mL fluid extract diluted in a glass of water, several times daily.

TOXICITY

Sage is likely to be safe when taken in amounts typically found in foods, although sage oil contains thujone, which may be toxic in large doses. In large amounts, the camphor and thujone content of sage oil have been shown to have convulsant properties in rats (Millet et al 1981) and when taken internally in large amounts, sage may cause restlessness and seizures in humans (Blumenthal et al 2000, Newell et al 1996). Sage tea has also been reported to cause cheilitis and stomatitis, dry mouth and local irritation.

ADVERSE REACTIONS

One double-blind, randomised trial found that it was well tolerated and produced fewer side effects than placebo (Akhondzadeh et al 2003). Occasional allergic reactions with topical use have been reported.

SIGNIFICANT INTERACTIONS

Iron, calcium, magnesium

Due to the tannin content, sage may reduce the absorption of these minerals — separate doses by 2–3 hours.

CONTRAINDICATIONS AND PRECAUTIONS

Sage oil can irritate the skin when used topically. Internal use of the essential oil should be closely monitored.

PREGNANCY USE

Traditionally, sage is reported to have abortifacient properties. Its use in pregnancy is therefore not recommended (Mills & Bone 2000, Newell et al 1996).

PRACTICE POINTS/PATIENT COUNSELLING

- Sage is a widely used, popular spice and sage oil is used in a variety of culinary applications.
- Sage has a long history of use in traditional medicine as an antispasmodic and carminative, to relieve excess sweating and as a gargle for inflammations of the mouth.
- It is also commonly prescribed in combination with other herbs to relieve menopausal symptoms such as night sweats.
- Sage contains volatile oils and tannins that are thought to be the key constituents responsible for most of its pharmacological actions.
- It also has antibacterial and some antifungal activities.
- A recent double-blind study suggests it may be useful in mild-to-moderate Alzheimer's disease. Other studies report that it improves memory in healthy subjects.
- Sage is likely to be safe when taken in amounts typically found in foods.

PATIENTS' FAQs

What will this herb do for me?

Sage is used to reduce symptoms of menopause such as night sweats; however, scientific testing has not been conducted to confirm whether it is effective. Recent research suggests that it may improve memory in Alzheimer's disease and in healthy subjects.

When will it start to work?

The study in Alzheimer's disease found effects established within 4 months' use. In the case of menopause, a time frame is unknown.

Are there any safety issues?

When used in appropriate doses, it appears to be a safe herbal medicine; however, it should not be used in pregnancy.

St John's wort

HISTORICAL NOTE St John's wort (SJW) has been used medicinally since ancient Greek times when, it is believed, Dioscorides and Hippocrates used it to rid the body of evil spirits. Since the time of the Swiss physician Paracelsus (c. 1493–1541), it has been used to treat neuralgia, anxiety, neurosis and depression. Externally, it has also been used to treat wounds, bruises and shingles. The name 'St John's wort' is related to its yellow flowers, traditionally gathered for the feast of St John the Baptist and the term 'wort' is the old English word for plant. SJW has enjoyed its greatest popularity in Europe and comprises 25% of all antidepressant prescriptions in Germany (Schrader 2000). In the past few decades, its popularity has grown in countries such as Australia and the United States.

OTHER NAMES

Amber, balsana, devil's scourge, goatweed, hardhay, hartheu, herb de millepertuis, hierba de San Juan, hypericum, iperico, johanniskraut, klamath weed, konradskraut, millepertuis, rosin rose, sonnenwendkraut, St Jan's kraut, tipton weed, witch's herb

BOTANICAL NAME/FAMILY

Hypericum perforatum (family Clusiaceae or Guttiferae)

PLANT PARTS USED

Aerial parts, flowering tops

CHEMICAL COMPONENTS

Naphthodianthrones (including hypericin and pseudohypericin). Flavonoids, mostly hyperoside, rutin, quercetrin, isoquercitrin, quercetin and kaemferol, phenolics, including hyperforin, procyanidins, essential oil, sterols (beta-sitosterol), vitamins C and A, xanthones and choline.

Manufactured products will vary in the concentrations and proportions of the different plant constituents present because these are influenced by the plant's place of origin, its harvest time and drying, extraction processes and storage conditions. Hyperforin, in particular, can be present in variable concentrations because it is unstable in light, air and most organic solvents (Mennini & Gobbi 2004). This is extremely important to remember when comparing studies, as variations in chemical composition could be responsible for differences in results. It also provides a rationale for lack of interchangeability between brands.

MAIN ACTIONS

Due to the combined effect of several active constituent groups, SJW has many pharmacological actions.

Antidepressant

Although SJW has been investigated extensively in scientific studies, there are still many questions about its pharmacology and mechanisms of action.

Collectively, the data show that SJW extract exerts significant pharmacological activity within several neurochemical systems believed to be implicated in the pathophysiology of depression.

Inhibits synaptic reuptake of several neurotransmitters

Preclinical animal studies have found that SJW inhibits the synaptic reuptake system for serotonin, noradrenaline and dopamine (Nathan 1999, Wonnemann et al 2001). Studies using specific isolated constituents have demonstrated potent uptake inhibition of gamma aminobutyric acid (GABA) and L-glutamate in vivo (Bilia et al 2002, Chatterjee et al 1998). These effects appear to be non-competitive, dose-dependent and mediated via sodium channels (Roz & Rehavi 2004). Studies with hyperforin have shown that it acts by reducing the pH gradient across the synaptic vesicle membrane, resulting in diffusion of uncharged monoamines out of the vesicular compartment into the cytoplasm. The increase in cytoplasmic concentration in turn decreases the transmembrane gradient of the neurotransmitters causing an 'apparent' inhibition of synaptosomal uptake by hyperforin. This is a novel mechanism of action, which differs from conventional antidepressant drugs.

Although hyperforin is the main constituent responsible for these effects, tests now show that a number of others are also involved (Gobbi et al 2001), such as adhyperforin, which has demonstrated a strong inhibitory effect on neurotransmitter uptake, and the oligomeric procyanidins fraction, which has demonstrated weak-to-moderate effects (Wonnemann et al 2001).

GABA receptor binding

SJW extracts have been shown to bind at GABA-A and -B receptors, to inhibit GABA reuptake, to evoke GABA release from synaptosomes and to exert an anxiolytic effect that is blocked by the benzodiazepine antagonist flumazenil (Perfumi et al 2002).

Upregulation of serotonin receptors

SJW significantly upregulates both 5-HT_{1A} and 5-HT_{2A} receptors and has a significant affinity for opiate sigma receptors, which may contribute to the antidepressant effect (Teufel-Mayer & Gleitz 1997).

Dopamine beta-hydroxylase inhibition

Studies on isolated constituents showed that hypericin and pseudohypericin can inhibit the enzyme dopamine beta-hydroxylase in vitro (Bilia et al 2002).

Inhibition of catechol-O-methyltransferase

This has been demonstrated in test tube studies (Thiede & Walper 1994).

Suppresses IL-6 synthesis

Various extracts from SJW produce a potent and dose-dependent inhibition of substance P-induced IL-6 synthesis (Fiebich et al 2001), which may also contribute to the herb's overall antidepressant effect.

Clinical note — Pharmacologically important constituents

It has generally been considered that most of the pharmacological activities of SJW are attributable to hypericin and the flavonoid constituent, hyperforin. Besides contributing to the antidepressant activity, hypericin is the primary constituent responsible for the photosensitivity reactions reported with high intakes. Hyperforin is also a major contributor to the herb's antidepressant activity (Butterweck et al 2003a, Mennini & Gobbi 2004) and considered the main constituent responsible for inducing the cytochrome P-glycoprotein and thereby producing drug interactions. Besides this, it demonstrates many other pharmacological effects such as antibacterial, anti-inflammatory and antineoplastic activities. Components previously considered void of activity have also been identified as important for pharmacological activity. For example, both procyanidin B2 and hyperoside increase the oral bioavailability of hypericin by 58% and 34%, respectively, and therefore, its clinical effects (Butterweck et al 2003b). A report published in June 2003 demonstrated that an extract devoid of both hyperforin and hypericin still exhibited antidepressant activity (Butterweck et al 2003a). Other constituents with antidepressant activity were identified and include hyperoside, isoquercitrin and miquelianin, and the 3-O-galactoside, 3-O-glucoside and 3-O-glucuronide of quercetin.

Monoamine oxidase (MAO) inhibition

Inhibition of MAO by hypericin demonstrated in vitro was believed to be the primary mode of action; however, this has not been confirmed in several subsequent studies that have shown only weak inhibitory activity at doses in excess of usual therapeutic levels (Di Carlo et al 2001).

Antiretroviral and antibacterial

Although in vitro and studies in animal models have identified antiretroviral activity for hypericin and pseudohypericin (Meruelo et al 1988), two clinical trials could not confirm these effects, even when larger doses of hypericin were administered (Gulick et al 1999, Jacobson et al 2001).

The mechanism involved is not known; however, it is suspected to involve direct inactivation of the virus or prevention of virus shedding, budding or assembly at the cell membrane (Meruelo et al 1988). The presence of light is an important requirement for antiretroviral activity to be demonstrated, as the effect appears to be photoactivated (Hudson et al 1993, Miskovsky 2002).

Hyperforin has also demonstrated antiviral and antibacterial activities (Medina et al 2006). Hyperforin exhibits effective antibacterial activity against methicillin-resistant *Staphylococcus aureus* (MRSA) and other gram-positive bacteria, but no growth-inhibitory effect on gram-negative bacteria or *Candida albicans* (Schempp et al 1999).

Anxiolytic

Several in vivo studies confirm the anxiolytic effects of SJW extract (Beijamini & Andreatini 2003, Jakovljevic et al 2000, Vandenbogaerde et al 2000). Activity at the GABA receptors and an increase in circulating GABA levels are likely to be involved.

Anti-inflammatory and analgesic

Both in vitro and in vivo testing has identified anti-inflammatory and analgesic activities for SJW (Jakovljevic et al 2000, Raso et al 2002). It potently inhibits binding to mu-, delta- and kappa-opioid receptors (Simmen et al 1998). In vivo tests also identify modulation of COX-2 expression for hypericum extract (Raso et al 2002). Studies with the isolated constituent hyperforin have shown that it potently inhibits COX-1 and 5-lipo-oxygenase in vitro (Albert et al 2002). Quercetin and other flavonoids contribute to the anti-inflammatory effect.

Anticancer effects

Hypericin, the photoactive compound of *Hypericum perforatum*, is probably the most powerful photosensitiser found in nature (Kacerovska et al 2008). It has minimal toxicity but exhibits potent photo-damaging effects in the presence of light (Olivo et al 2006). It is known to generate a high yield of singlet oxygen and other reactive oxygen species that are associated with photo-oxidative cellular damage. The application of photodynamic therapy (PDT) with hypericin for the treatment of cancers such as recurrent mesothelioma and skin cancer has been validated in clinical trials. It may also have potential as a photodynamic agent in the treatment of nasopharyngeal cancer (NPC) according to in vitro and in vivo models (Kacerovska et al 2008).

Hyperforin also exhibits antineoplastic potential based on the sum of its anticarcinogenic, antiproliferant, pro-apoptotic, anti-invasive and antimetastasic effects (Medina et al 2006). Hyperforin has been shown to effectively decrease the proliferation rates of a number of mammalian cancer cell lines, induce apoptosis of tumour cells and inhibit angiogenesis both in vitro and in vivo. Besides hypericin and hyperforin, polyphenolic procyanidin B2 has also demonstrated an inhibitory effect on the growth of leukaemia cells, brain glioblastoma cells and normal human astrocytes in vitro (Hostanska et al 2003). Further, the inhibitory effects on leukaemic cell growth were synergistically strengthened when hypericin and hyperforin were tested together.

Reduces alcohol intake

Several reports indicate comorbidity between depression and ethanol abuse and that depressive disorders and ethanol abuse may be associated with similar changes in the activity of central neurotransmitters (Markou et al 1998). In vivo studies using SJW in animal models of alcoholism have found that it does not alter food and water intakes, or the pharmacokinetics of alcohol, but a reduction in ethanol intake occurs (Panocka et al 2000).

Cognitive effects

SJW extracts and hyperforin improve cognitive function in experimental models (Kiewert et al 2004); however, clinical studies have been less convincing (Siepmann et al 2002, Timoshanko et al 2001). In vivo studies with hyperforin have found that it induces the release of acetycholine from cholinergic terminals in the hippocampus and striatum, providing an explanation for the observed effects. Preventive administration of *Hypericum perforatum* (350 mg/kg PO) counteracted the working memory impairments caused by repeated stress in male Wistar rats. The herb significantly improved hippocampus-dependent spatial working memory in comparison with control ($P < 0.01$) and alleviated some other negative effects of stress on cognitive functions (Trofimiuk & Braszko 2008).

> ***Clinical note — PDT for tumour cells***
> PDT involves the administration of a photosensitiser, which is taken up and stored within tumour cells, followed by light irradiation with a specific wavelength, giving rise to irreversible tissue destruction (Kacerovska et al 2008). It is aimed at destroying tumour cells without damaging surrounding normal tissues (Agostinis et al 2002). This combination approach results in the production of cytotoxic oxygen singlets within the tumour that cause irreversible cellular damage and tumour destruction.

Antispasmodic

SJW exhibits antispasmodic activity, according to research conducted with an experimental animal model (Jakovljevic et al 2000), most likely mediated via GABA activity.

Inhibits gastric motility

Among the chemical constituents of SJW extract tested, hyperforin and, to a lesser extent, the flavonoids kaempferol and quercitrin, inhibited acetylcholine-induced contractions in an animal model (Capasso et al 2008). SJW has a direct inhibitory effect on smooth muscle and could also possibly modulate gastric neurotransmission.

OTHER ACTIONS

No clinically significant effect on platelet aggregation has been identified (Beckert et al 2007)

Induction of CYP3A4 activity in the intestinal wall

Human studies have identified CYP3A4 and 2C19 induction effects for standard SJW extracts (e.g. LI 160), but no effects on CYP1A2, CYP2C9 or CYP2D6 (Durr et al 2000, Gurley et al 2008a, Jiang et al 2004, Wang et al 2001, 2004a). Human studies have failed to identify significant CYP3A4, 2D6, 2C9, 1A2 or 2C19 induction for low-hyperforin SJW extracts, such as ZE 117, using the appropriate probe drugs (Arold et al 2005, Madabushi et al 2006, Mueller et al 2004).

Hyperforin is a potent ligand for the pregnane X receptor, an orphan nuclear receptor that regulates expression of the CYP3A4 mono-oxygenase (Moore et al 2000). Although it is considered the chief constituent responsible for the pharmacokinetic interactions reported, there are other, less potent constituents in SJW, which also modulate cytochrome enzymes (Obach 2000).

Results from an open-label clinical study suggest that the effects of standard SJW (LI 160) on CYP3A4 enzymes may be biphasic, where the initial dose leads to a minor inhibition, followed by significant induction during long-term use (Rengelshausen et al 2005). Clinical studies indicate that CYP3A activity returns progressively to the basal level approximately 1 week after cessation of SJW administration (Imai et al 2008).

Increases levels of intestinal P-glycoprotein (P-gp)

SJW extract produced a 3.8-fold increase of intestinal P-gp expression in vivo (Durr et al 2000). Hyperforin has been identified as the key constituent responsible for P-gp induction effects (Tian et al 2005), although in vitro tests suggest other less potent constituents also exist such as quercetin, hypericin, biapigenin and kaempferol (Patel et al 2004, Weber et al 2004).

Once again, low-hyperforin SJW extracts do not appear to significantly induce P-gp (Arold et al 2005, Madabushi et al 2006, Mueller et al 2004).

In vitro and in vivo tests further indicate that P-gp effects caused by standard SJW (LI 160) are biphasic with an initial inhibitory effect followed by induction after longer exposure (Rengelshausen et al 2005, Wang et al 2004a).

CLINICAL USE

Up until recently, most trials conducted with SJW used a 0.3% hypericin water and alcohol extract known as LI 160. Subsequently, studies using different preparations, such as WS 5573 (standardised to hyperforin) or ZE 117 (a low concentration hyperforin preparation), have been tested.

Depression

There is now strong evidence from several meta-analyses to conclude that SJW extract is an effective treatment in mild, moderate and severe depressive disorder with efficacy comparable to tricyclic and selective serotonin reuptake inhibitor (SSRI) antidepressant drugs. Additionally, SJW is well tolerated and induces less adverse events than pharmaceutical antidepressants. There is also evidence indicating that it reduces relapse.

Mild-to-moderate depression

SJW has shown efficacy as a successful treatment for mild-to-moderate depression in numerous double-blind, placebo-controlled trials, confirmed by several meta-analyses.

The most recent Cochrane review released in 2005 analysed data from 37 double-blind, randomised studies (n = 4925) that used monopreparations of SJW over a treatment period of at least 4 weeks (Linde et al 2005). It concluded that hypericum extracts improved symptoms more than placebo and produced effects similar to synthetic antidepressants (tricyclics and SSRIs) in adults with mild-to-moderate depression.

This confirms the results obtained in two earlier meta-analyses (Linde & Mulrow 2000, Whiskey et al 2001).

Subsequently, a double-blind study of 388 patients with moderate depression has found SJW extract (900 mg daily of extract STW3-VI) to be as effective as citalopram (20 mg daily) ($P < 0.0001$) (Gastpar et al 2006). The HDS scores were reduced to 10.3 ± 6.4 for SJW extract, 10.3 ± 6.4 for citalopram and 13.0 ± 6.9 for placebo and both antidepressants were significantly more effective than placebo. At the end of treatment, 54.2% of the SJW group and 55.9% of the citalopram group were assessed as responders compared with 39.2% for placebo. With regard to safety, significantly more adverse events were documented in the

Clinical note — The Hamilton Depression Scale (HDS)

The HDS is an observer-rated scale that focuses mainly on somatic symptoms of depression. Although the original version included 21 items, a similar version using 17 items is more commonly used in clinical trials. Most studies using the HDS report the number of 'treatment responders' (patients achieving a score less than 10 and/or less than 50% of the baseline score) (Linde et al 2005).

citalopram group (53.2%) than for SJW (17.2%) or placebo (30%).

Kasper et al re-analysed data from of a subset of patients ($n = 217$) suffering from an acute episode of mild depression from controlled trials testing SJW extract WS 5570 (Kasper et al 2008a). The analysis shows that SJW extract WS 5570 has a meaningful beneficial effect during acute treatment of patients suffering from mild depression and leads to a substantial increase in the probability of remission. The studies tested three different doses, 600, 900, or 1200 mg/day or placebo for 6 weeks. Patients receiving active treatment with WS 5570 experienced decreases in the Hamilton depression scale (HDS) total score by an average of 10.8 (600 mg/day), 9.6 (900 mg/day), and 10.7 (1200 mg/day) points between the pretreatment baseline value and the end of acute treatment, compared to 6.8 points in the placebo group. All differences were significant. The rates of responders were 73%, 64%, 71% and 37% for WS 5570 600 mg/day, 900 mg/day and 1,200 mg/day and placebo, respectively.

Paediatric use

Results from a postmarketing surveillance study of 101 children under 12 years with mild-to-moderate depression has suggested that SJW may be an effective and well-tolerated treatment in this population (Hubner & Kirste 2001). The number of physicians rating effectiveness of treatment with SJW as 'good' or 'excellent' was 72% after 2 weeks, 97% after 4 weeks and 100% after 6 weeks and ratings by parents were similar. Although encouraging, it is difficult to interpret the clinical significance of the results, as there was no placebo group and the final evaluation included only 76% of the initial sample.

An 8-week open pilot study was conducted with SJW (300 mg three times daily) in 26 adolescents with major depressive disorders (MDDs) (Simeon et al 2005). The subjects were aged 12–17 years (mean, 14.8 years). Only 11 patients completed the study of which 9 (82%) showed significant clinical improvement based on Clinical Global Improvement change scores. Once again, interpretation of these results is hampered by a large drop-out rate.

Preventing relapse of depression

A double-blind, placebo-controlled, multicentre trial conducted by Kasper et al evaluated the efficacy and safety of hypericum extract WS 5570 in preventing relapse during 6 months' continuation treatment and 12 months' long-term maintenance treatment after recovery from an episode of recurrent depression (Kasper et al 2008b). After 6 weeks of single-blind treatment with 3 × 300 mg/day WS 5570 patients with score ≤2 on item 'Improvement' of the Clinical Global Impressions (CGI) scale and a HDS total score decrease ≥50% versus baseline were randomised to 3 × 300 mg/day WS 5570 or placebo for 26 weeks. This provided a total of 426 patients in the next study phase. Treatment with WS 5570 showed more favourable HDS and Beck Depression Inventory time courses and greater overall improvement (CGI) than controls. In long-term maintenance treatment, a pronounced prophylactic effect of WS 5570 was observed in patients with an early onset of depression as well as in those with a high degree of chronicity. Adverse event rates under WS 5570 were comparable to placebo.

Clinical note — Low hyperforin extracts effective?

Considering that hyperforin demonstrates significant antidepressant activity, it is important to evaluate whether low-hyperforin-containing SJW preparations remain effective. Three randomised, double-blind studies that have compared low-hyperforin extracts (ZE 117) to fluoxetine or imipramine suggest that the absence of hyperforin does not hinder the antidepressant effect (Friede et al 2001, Schrader 2000, Woelk 2000).

Major depression

Although a 2005 Cochrane review stated that SJW shows only minimal benefits over placebo in major depression (Linde et al 2005) an updated 2008 Cochrane systematic review has concluded that hypericum extracts: (a) are superior to placebo in patients with major depression; (b) are similarly effective as standard antidepressants (SSRIs and tricyclics); and (c) have fewer side effects than standard antidepressants (Linde et al 2008). A total of 29 randomised trials were evaluated ($n = 5489$), including 18 comparisons with placebo and 17 comparisons with synthetic standard antidepressants. The standard antidepressants used as active comparators were fluoxetine (6 trials, dosage 20 to 40 mg), sertraline (4 trials, 50–100 mg), imipramine (in 3 trials, dosage 100–150 mg), citalopram (1 trial, 20 mg), paroxetine (1 trial, 20–40 mg), maprotiline (1 trial, 75 mg) and amitriptyline (1 trial, 75 mg). Most trials used a dose range 500 mg–1200 mg/day of SJW.

This result is clinically important as the effects of standard antidepressants over placebo are modest and although SSRIs are better tolerated than older antidepressant drugs (such as MAOIs), side effects are still common.

Comparisons to SSRI drugs in major depression

A meta-analysis compared the efficacy and tolerability of hypericum with SSRIs as a group of standard antidepressants. Thirteen randomised, placebo-controlled clinical trials were included in the analysis, which found that hypericum does not differ from SSRIs according to efficacy and adverse events in MDD. Hypericum was better tolerated, as there were lower withdrawal rates due to adverse events by hypericum, which is an advantage in management of MDD (Rahimi et al 2009).

Commission E approves the use of SJW for psychovegetative disturbances, depressive moods, anxiety and nervous unrest (Blumenthal et al 2000).

Obsessive-compulsive disorder

Treatment with a fixed dose of 450 mg of SJW containing 0.3% hypericin twice daily over 12 weeks improved the condition in 5 of 12 patients,

Clinical note — Relative safety of SJW compared with pharmaceutical antidepressants

Much has been made of the known or suspected risks associated with the use of SJW, with far too little discussion focusing on the decisive question of its relative safety compared with pharmaceutical antidepressants. It has been estimated that approximately 1 in 30,000 people using SJW will experience an adverse reaction, including those attributed to drug interactions (Schulz 2006). An overview of 16 postmarketing surveillance studies involving different SJW preparations and 34,804 patients found that side-effect incidence varied from 0 to 2.8% in short-term studies (4–6 weeks) and 3.4–5.7% in long-term studies (52 weeks) (Linde & Knuppel 2005). Gastrointestinal symptoms, sensitivity to light and other skin conditions and agitation were the most commonly reported side effects and were generally described as mild. The review found that serious side effects or interactions were not reported by any study. Taking this into account, the incidence of side effects to SJW is approximately 10-fold lower than for conventional antidepressants (SSRIs) (Schulz 2006). The most common adverse event among spontaneous reports is photosensitivity, which is estimated to occur in 1 in 300,000 treated cases. This can occur with a dose of 5–10 mg/day hypericin, which is 2–4-fold higher than the recommended dose. SJW has no significant effect on blood pressure or heart rate (Siepmann et al 2002), making it a safer choice than tricyclic antidepressants in patients with cardiovascular disease. It also lacks atropinic activity, so side effects such as dry mouth, urinary retention and blurred vision do not occur. In addition, the common side effects reported for SSRIs, such as anorexia, insomnia, sexual dysfunction, excessive sweating and visual disturbance, have not been reported for SJW. Similar to all standard antidepressants, SJW can interact with other medicines and needs to be judiciously prescribed.

according to an open study (Taylor & Kobak 2000).

Seasonal affective disorder (SAD)

Wheatley found that people with mild-to-moderate SAD experienced significant improvements with anxiety, loss of libido and insomnia after 8 weeks' treatment with SJW (Wheatley 1999). The test group receiving SJW extract (Kira 300 mg) three times daily plus light therapy experienced superior sleep compared with the group receiving SJW as stand-alone treatment.

Polyneuropathy

Although SJW is sometimes used for nerve pain, a randomised, double-blind, crossover study of 54 patients identified a trend towards lower total pain score with SJW treatment, although none of the individual pain ratings were significantly changed (Sindrup et al 2001). The dose of SJW used provided 2.7 mg/day total hypericin and was taken over 5 weeks.

Menopause: psychological and psychosomatic symptoms

In at least one trial, SJW has been investigated as sole therapy in menopausal and premenopausal women with psychological and psychosomatic symptoms. After 12 weeks' treatment with 900 mg hypericum (Kira 300 mg three times daily) symptoms diminished or disappeared completely in the majority of women (76.4% by patient evaluation and 79.2% by physician evaluation). Interestingly, sexual wellbeing also improved in 80% of cases (Grube et al 1999).

In combination

Another study investigated a fixed combination of isopropanolic black cohosh (Remifemin; standardised to 1 mg triterpene glycosides) and ethanolic SJW (standardised to 0.25 mg total hypericin) in 301 women with menopausal symptoms with pronounced psychological symptoms (Uebelhack et al 2006). The double-blind, randomised study found that 16 weeks of herbal treatment produced a significant 50% reduction in the Menopause Rating Scale score compared to 20% with placebo and a significant 42% reduction in the HDS score compared to only 13% in the placebo group.

A second study testing the effectiveness of combined SJW and black cohosh found that combination therapy was superior to stand-alone black cohosh therapy for the treatment of climacteric mood symptoms in general practice (Briese et al 2007). This was a prospective, controlled, open-label observational study which involved 6141 women attending 1287 outpatient gynaecologists in Germany.

Perimenopause

Symptomatic perimenopausal women aged 40–65 years who experience hot flushes (three or more per day) may experience significant improvements to menopause-specific quality of life using SJW extract (900 mg t.i.d.) according to a double-blind, placebo-controlled study (Al-Akoum et al 2009). After 3 months of treatment, herbal treatment was significantly better than placebo for menopause-specific quality of life and also provided significant improvements for self-reported sleep problems. No significant effects were seen at 6 weeks indicating that the effects have slow onset.

Premenstrual syndrome (PMS)

An open study in patients with PMS found that a low dose of 300 mg SJW daily produced significant reductions in all outcome measures. The degree of improvement in overall PMS scores between baseline and the end of the trial was 51%, with over two-thirds experiencing at least a 50% decrease in symptom severity (Stevinson & Ernst 2000).

Herpes infection
Based on its antiviral activity, SJW is also used clinically in the treatment of herpes virus infections. One study of unknown design found that oral extract LI 160 (over a period of 3 months) reduced the frequency and severity of episodes of recurrent herpes labialis and herpes genitalis (Mannel et al 2000).

Smoking cessation
Preliminary evidence from experimental models suggests that SJW may be of use in reducing nicotine withdrawal signs. In the study, SJW significantly and dose-dependently reduced the total nicotine abstinence score (Catania et al 2003). Further studies are required to determine its usefulness for smoking cessation treatment in humans.

Topical use

Atopic dermatitis
A cream containing SJW extract (standardised to 1.5% hyperforin) was shown to reduce the intensity of eczematous lesions when used twice daily in a prospective, double-blind study (Schempp et al 2003a). Beneficial effects were already observed at the first review, which was on day 7.

Treatment of acute and contused injuries
No controlled studies are available, but anti-inflammatory, analgesic and bactericidal activities provide a theoretical basis for its use.

Commission E approves the topical use of oily SJW preparations for this indication (Blumenthal et al 2000).

Myalgia
Although no controlled studies are available, anti-inflammatory and analgesic activities provide a theoretical basis for its use in this condition.

Commission E approves the topical use of oily SJW preparations for this indication (Blumenthal et al 2000).

First-degree burns
Although no controlled studies are available, anti-inflammatory, analgesic and bactericidal activities provide a theoretical basis for its use in this condition.

Commission E approves the topical use of oily SJW preparations for this indication (Blumenthal et al 2000).

PDT
A prospective study aimed at investigating the efficacy of PDT with topical application of an extract of *H. perforatum* in actinic keratosis, basal cell carcinoma (BCC) and morbus Bowen (carcinoma in situ) was conducted with 34 patients (8 with actinic keratoses (AKs), 21 with BCC and 5 with Bowen's disease) (Kacerovska et al 2008). Hypericum extract was applied on the skin lesions under occlusion and followed by irradiation with 75 J/cm^2 of red light 2 h later. The treatment was performed weekly for 6 weeks on average. The percentage of complete clinical response was 50% for AKs, 28% in patients with superficial BCC and 40% in patients with Bowen's disease. There was only a partial remission seen in patients with nodular BCCs. A complete disappearance of tumour cells was found in the histologic preparation of 11% of patients with superficial BCCs and 80% in the patients with Bowen's disease. Unfortunately, the combined treatment was poorly tolerated as all patients complained of burning and painful sensations during irradiation.

Attention deficit hyperactive disorder (ADHD)
A randomised, double-blind, placebo-controlled trial found that SJW (300 mg three times daily of *H. perforatum* standardised to 0.3% hypericin) was ineffective for the symptomatic treatment of ADHD in children (Weber et al 2008). The study involved 54 children aged 6–17 years who met Diagnostic and Statistical Manual of Mental Disorders (Fourth Edition) criteria for ADHD by structured interview and was conducted over 8 weeks.

OTHER USES
In practice, SJW is also used to treat fibrositis, nervous exhaustion, sciatica and gastrointestinal conditions, such as oesophagitis and peptic ulcers. Traditionally, SJW has been used for wound healing, diuretic, melancholy, pain relief, treatment for snake bites, bedwetting in children, malaria and psychosis.

DOSAGE RANGE
- Dried herb: 2–5 g/day.
- Liquid extract (1:2): 3–6 mL/day.
- Tincture (1:5): 7.5–15 mL/day.
- Standardised extract containing 1.0–2.7 mg total hypericin daily.
- It is advised that patients using SJW long term should have their doses reduced slowly when discontinuing its use.

External use
- Oily macerate: Macerate flowering tops in olive oil for several weeks and stir often, then drain through a gauze. Store in a dark bottle out of direct light. Apply oil directly to the affected area. To promote extraction of flavonoids, store in a sunny area for 6 weeks (oil will turn red).

According to clinical studies
Doses are for dried herb or equivalent.
- Mild-to-moderate depression: adult — doses ranging from 350–1800 mg/day have been used; children (aged 6–12 years) — 200–400 mg/day in divided doses.

  The extract most often studied is LI 160, although others have also been tested, such as WS 5573 (standardised to hyperforin), ZE 117 (a low concentration hyperforin preparation), WS 550 and STW3-V1.
- Major depression: 500 mg–1800 mg/day in divided doses.
- Obsessive compulsive disorder (OCD): 450 mg twice daily of an extract containing 0.3% hypericin.
- Menopausal symptoms: 900 mg/day in divided doses.

- PMS: 300 mg/day (standardised to 900 microgram hypericin).
- SAD: 900 mg/day in divided doses.

ADVERSE REACTIONS

It has been estimated that approximately 1 in 30,000 people using SJW will experience an adverse reaction, including those attributed to drug interactions (Schulz 2006). The incidence of side effects to SJW is approximately 10-fold lower than for conventional antidepressants (SSRIs). According to an overview of 16 post-marketing surveillance studies, gastrointestinal symptoms, sensitivity to light and other skin conditions and agitation were the most commonly reported side effects and were generally described as mild (Linde & Knuppel 2005).

Photosensitivity (unlikely at therapeutic doses)

The most common adverse event among spontaneous reports is photosensitivity, which is estimated to occur in 1 in 300,000 treated cases. This can occur with a dose of 5–10 mg/day hypericin, which is 2–4-fold higher than the recommended dose. Commission E has noted the possibility of photosensitivity reactions, particularly in fair-skinned people.

SIGNIFICANT INTERACTIONS

SJW is one of the few herbal medicines that has been subjected to controlled studies in order to determine the significance of its interaction with numerous drugs. Although this can be reassuring, the clinical significance of many interactions is still unpredictable because of the variable chemical composition of products.

It is important to note that interactions due to CYP and P-gp induction do not appear clinically significant with low-hyperforin extracts (ZE 117). This was recently confirmed in a clinical study testing SJW powder with low hyperforin content which was shown to cause a mild induction of CYP3A which was not considered clinically relevant (Mueller et al 2009).

Clinical note — Mechanisms responsible for reported interactions

Based on the herb's pharmacology, there are several mechanisms by which it may interact with drugs. Considering that SJW has significant serotonin reuptake inhibitor activity and significantly upregulates both 5-HT_{1A} and 5-HT_{2A} receptors, concomitant use of drugs that elevate serotonin levels, such as tricyclic antidepressants or SSRIs, may result in additive or synergistic effects and increase the risk of serotonergic syndrome. As the constituent hyperforin has a significant and selective induction effect on CYP3A4 and 2C19 activity (Durr et al 2000, Wang et al 2001) and induces the drug transporter P-gp, a number of pharmacokinetic interactions are possible with those drugs that are substrates for CYP3A4 or 2C19 and/or rely on P-gp transport. Refer to Chapter 8 for further information on interactions with herbs and natural supplements.

Alprazolam

Decreases serum levels of alprazolam via CYP induction. Monitor for signs of reduced drug effectiveness and adjust the dose if necessary or avoid.

Amitriptyline

Although SJW decreases serum levels of amitriptyline via CYP induction in vivo (Johne et al 2002), theoretically it could also induce increases in serotonin availability, which has an opposite effect; the clinical outcome of these two interacting mechanisms is unknown — monitor for signs of changed drug effectiveness and adjust the dose if necessary or avoid concurrent use.

Antidepressants (SSRIs and SNRIs)

Increased risk of serotonin syndrome possible; however, increased antidepressant activity is also possible with appropriate doses — avoid concurrent use unless under medical supervision, so that doses may be altered appropriately.

Anticonvulsants

Phenobarbitone, phenytoin: SJW may increase drug metabolism resulting in reduced drug efficacy — avoid concurrent use unless under medical supervision, so that doses may be altered appropriately.

Antineoplastic drugs

Irinotecan (Mathijssen et al 2002), imatinib mesylate etc. which are P-gp and/or CYP3A4 substrates — avoid (see Chapter 10 for more information on safety of complementary medicines and cancer).

Atorvastatin

SJW reduces the efficacy of atorvastatin, so lipid-lowering effects are compromised, according to a clinical study which tested a product called Movina (containing 300 mg of *Hypericum perforatum*) taken as one tablet twice daily (Andren et al 2007).

Cisplatin

Cisplatin-induced histological abnormality of the kidney was blocked by pretreatment with SJW in vivo (Shibayama et al 2007). Total and free cisplatin concentration in serum was not influenced by SJW treatment suggesting that this may be a beneficial interaction under professional supervision.

Cyclosporin

Decreases plasma levels of cyclosporin significantly within 3 days of concomitant use via CYP induction (Bauer et al 2003) — avoid concurrent use.

A pharmacokinetic study with kidney graft recipients suggests that the effect is not significant when low-hyperforin products are used (Madabushi et al 2006).

Digoxin

Decreases serum digoxin levels significantly within 10 days of concomitant use (Johne et al 1999), chiefly due to induction of the P-gp. The

interaction between digoxin and SJW in humans has been confirmed more recently by Gurley et al and is clinically significant (Gurley et al 2008b) — monitor patient for signs of reduced drug effectiveness and adjust the dose if necessary or avoid concurrent use.

Gliclazide
Treatment with SJW significantly increases the apparent clearance of gliclazide, which is independent of CYP2C9 genotype, according to a crossover clinical study (Xu et al 2008). People with diabetes receiving this combination should be closely monitored to evaluate possible signs of reduced efficacy.

HIV non-nucleoside transcriptase inhibitors
Decreases serum levels — avoid concurrent use.

HIV protease inhibitors
Decreases serum levels — avoid concurrent use.

Methadone
Decreases serum levels via CYP induction — avoid concurrent use (Eich-Hochli et al 2003).

Midazolam
Decreases serum levels of midazolam via CYP induction — monitor for signs of reduced drug effectiveness and adjust the dose if necessary or avoid.

Nifedipine
SJW was shown to induce nifedipine metabolism in vivo (Wang et al 2007) — monitor for signs of reduced drug effectiveness and adjust the dose if necessary or avoid.

Omeprazole
Decreases serum levels via CYP induction (Wang et al 2004b) — monitor for signs of reduced drug effectiveness and adjust the dose if necessary or avoid.

Oral contraceptives
Breakthrough bleeding has been reported, which can indicate decreased effectiveness of oral contraceptives. In 2003, a controlled study confirmed that standard doses of SJW cause an induction of ethinyl oestradiol–norethindrone metabolism consistent with increased CYP3A activity (Hall et al 2003) — use this combination with caution.

In 2002, a pharmacokinetic study found no significant interaction between low-hyperforin SJW and low-dose oral contraceptives (Madabushi et al 2006). This has been confirmed in a further clinical study using a SJW extract (Ze 117) with low hyperforin content on the pharmacokinetics of ethinylestradiol and 3-ketodesogestrel (Will-Shahab et al 2009) — low-hyperforin extracts appear to be safe.

PUVA therapy
High-dose hypericin may increase sensitivity to UV radiation — caution is advised.

Simvastatin
Decreases serum levels of simvastatin via CYP induction (Sugimoto et al 2001) — monitor for signs of reduced drug effectiveness and adjust the dose if necessary (no interaction is expected with pravastatin).

Tacrolimus
Decreases serum levels of tacrolimus via CYP induction (Mai et al 2003) — avoid this combination.

Verapamil
Decreases serum levels of verapamil via CYP induction — monitor for signs of reduced drug effectiveness and adjust the dose if necessary.

Warfarin
Metabolism of warfarin is chiefly by CYP2C9, and a minor metabolic pathway is CYP3A4, so theoretically it may interact with SJW. A clinical study found no change to international normalised ratio (INR) or platelet aggregation (Jiang et al 2004), but there are case reports suggesting that SJW may lower the INR. Caution is advised — monitor INR.

CONTRAINDICATIONS AND PRECAUTIONS
People with fair skin undergoing UV treatment should use high doses of SJW with caution.

PREGNANCY USE
A systematic review of the literature for evidence on the use, safety and pharmacology of SJW focusing on issues pertaining to pregnancy found there is in vitro evidence from animal studies that SJW during pregnancy does not affect cognitive development nor cause long-term behavioural defects, but may lower offspring birth weight (Dugoua et al 2006). Although encouraging, safe doses in pregnant women have not yet been determined. In practice, it is not used in pregnancy.

SJW appears to be relatively safe in lactation (Dugoua et al 2006). A study of breastfeeding mothers indicated that low levels of hyperforin are excreted into breast milk; however, infant exposure is comparable to levels reported in most studies assessing antidepressants or neuroleptics and no side effects were seen in the mothers or infants (Klier et al 2006). The doses used were 300 mg of SJW (LI 160, three times daily).

PATIENTS' FAQs
What will this herb do for me?
SJW is an effective treatment for mild, moderate and severe depression and it reduces the risk of relapse. Its antidepressant effects are similar to pharmaceutical antidepressant drugs; however, it is better tolerated with less side effects. It may also be useful for PMS symptoms, SAD, OCD and for menopausal and premenopausal women with psychological and psychosomatic symptoms. The oily preparations are also used topically to treat burns, injuries, allergic dermatitis and muscle pain.

When will it start to work?
It often starts to exert beneficial effects in depression within 2–4 weeks of continuous use; however, maximal effects in other conditions may take longer.

Are there any safety issues?

SJW is well tolerated and has far less side effects than pharmaceutical antidepressant drugs, but it can interact with a number of different medications. Patients with clinically diagnosed depression should be under the care of a healthcare professional.

PRACTICE POINTS/PATIENT COUNSELLING

- SJW contains numerous constituents with pharmacological activity, including antidepressant, analgesic, anti-inflammatory, antispasmodic, anxiolytic, antineoplastic, antiviral and bactericidal activities.
- Numerous clinical studies support the use of SJW as an effective treatment for mild, moderate and severe depression. The most commonly studied extract is LI 160 although others have also been tested (e.g. WS 5573 (standardised to hyperforin), ZE 117 (a low concentration hyperforin preparation), WS 550 and STW3-V1). Clinical effects are comparable to tricyclic antidepressants and SSRIs; it also reduces the incidence of depression relapse.
- With regard to safety, SJW is better tolerated than standard antidepressants (SSRIs and tricyclics); however, it still needs to be prescribed judiciously to avoid interactions. Patients with clinically diagnosed depression should be under the care of a healthcare professional.
- Low-hyperforin-containing SJW extracts do not have the same interaction potential as standard SJW extracts and may present a safer option for some individuals.
- Preliminary human studies have suggested a possible role in PMS, SAD, OCD and in menopausal and premenopausal women with psychological and psychosomatic symptoms.
- Oily preparations have been used topically to treat burns, acute and contused injuries, atopic dermatitis and myalgia.

St Mary's thistle

HISTORICAL NOTE St Mary's thistle has a long history of traditional use since ancient times. Over the centuries, it has been touted as a remedy for snakebite, melancholy, liver conditions and promoting lactation. The name 'milk thistle' derives from its characteristic spiked leaves with white veins which, according to legend, were believed to carry the milk of the Virgin Mary.

OTHER NAMES

Carduus marianus, cardo blanco, cardo de burro, chandon marie, holy thistle, lady's milk, lady's thistle, Mariendistel, Marian thistle, Mary thistle, milk thistle, silybum, true thistle.

BOTANICAL NAME/FAMILY

Silybum marianum (family [Compositae] Asteraceae)

PLANT PART USED

Ripe seed

CHEMICAL COMPONENTS

Often silymarin is referred to as the active constituent of seeds from St Mary's thistle, but in fact it is a complex of at least seven flavonolignans. The principal component of silymarin is silybin (also referred to as silibinin), which makes up more than 50% of silymarin and is regarded as one of the most biologically active constituents (Jacobs et al 2002). Silybin is not a single compound either, but rather a mixture of two diastereoisomers, silybin A and silybin B (Kroll et al 2007). Other flavonolignans include isosilybin, silychristin and silydianin, all of which exist as diastereoisomers. A new flavonolignan, silyamandin, was discovered in St Mary's thistle preparations (MacKinnon et al 2007). St Mary's thistle seeds also contain a fixed oil comprising linoleic, oleic and palmitic acids, tocopherol and sterols, including cholesterol, campesterol, stigmasterol and sitosterol.

Schrieber et al found that the pharmacokinetics of silymarin was altered in patients with hepatitis C and non-alcoholic liver disease compared with healthy volunteers in a way that it correlates with highest caspase-3/7 activity (a measure of disease activity) (Schrieber et al 2008). Formulation research in dogs showed that the bioavailability of solid dispersion pellets is five times higher than that of a poorly water-soluble milk thistle extract (Sun et al 2008). Another in vivo study reported that a phytosome complex of phosphatidylcholine and silybin showed markedly enhanced bioavailability (Filburn et al 2007).

MAIN ACTIONS

Most investigation has used standardised preparations of St Mary's thistle, the silymarin constituent group or silybin.

Hepatoprotective effect

Protection of liver cells has been demonstrated against the following substances in vitro or in vivo:

- Carbon tetrachloride-induced liver cirrhosis (Chrungoo et al 1997, Mourelle et al 1989, Muriel & Mourelle 1990, Tsai et al 2008).
- Ethanol (Das & Vasudevan 2006).
- Paracetamol-induced liver peroxidation (Chrungoo et al 1997, Muriel et al 1992).
- Cyclosporin (von Schonfeld et al 1997).
- Phenothiazine (Palasciano et al 1994).
- Butyrophenone (Palasciano et al 1994).
- Erythromycin (Davila et al 1989).
- Amitriptyline and nortriptyline (Davila et al 1989).
- Oestradiol (Morazzoni & Bombardelli 1995).
- *Amanita phalloides* (Floersheim 1976, Vogel et al 1984).
- Tacrine (Galisteo et al 2000).
- Iron overload (Masini et al 2000, Pietrangelo et al 1995).
- Benzo(a)pyrene induced lung cancer (Kiruthiga et al 2007).

The exact mechanism of action has not been fully elucidated; however, several observations have been made which suggest that toxin blockade, antioxidant and free radical scavenging effects are among the most likely modes of actions. A study suggests that silymarin may be effective in protecting hepatocytes from saturated fatty acids-induced cell death (Song et al 2007).

Toxin blockade

Silymarin and silybin alter the structure of hepatocyte cell membranes by being incorporated into the hydrophobic–hydrophilic interface of the microsomal bilayer (Parasassi et al 1984). Silybin interacts with the surface rather than deeper regions of the bilayer, and therefore does not change significantly the biophysical properties of the deeper membrane regions (Wesolowska et al 2007). Additionally, inhibition of cyclic adenosine monophosphate (AMP)-dependent phosphodiesterase by silybin has been shown in vitro, which results in increased cAMP and stabilisation of lysosomal membranes (Koch et al 1985). Both actions alter cell membrane function and may be important for protecting the cell from toxin-induced damage. Alternatively, components in St Mary's thistle may bind to the hepatocyte cell membrane receptor site and inhibit binding of toxins to these sites (Jacobs et al 2002).

Chelates iron

Hepatic iron toxicity and fibrosis due to iron overload are mediated by lipid peroxidation of biological membranes and the associated organelles (Masini et al 2000). Both silymarin and silybin demonstrate protective effects against hepatic iron toxicity in vivo, primarily owing to antioxidant mechanisms. However, there is some evidence that iron chelation may also be involved (Borsari et al 2001, Masini et al 2000, Pietrangelo et al 1995, Psotova et al 2002). Serum ferritin levels, but not serum iron and transferring-iron saturation, were significantly decreased in patients with hepatitis C and Batts–Ludwig fibrosis stages II, III or IV following 12 weeks of treatment with silybin and soy phosphatidylcholine complex (IdB 1016). Stage III or IV fibrosis was independently associated with decreased post-treatment serum ferritin level (Bares et al 2008).

Liver regeneration/liver preservation

Silymarin accelerates the regeneration of hepatocytes after liver damage, according to an in vivo study. Silymarin was shown to increase hepatocyte protein synthesis by stimulating the activity of ribosomal RNA polymerase (Kropacova et al 1998). One study using isolated rat livers investigated whether silybin exerts protective effects in liver transplantation injury. It was found that liver preservation done in the presence of silybin improved parameters affected by preservation and reperfusion, thus it increased adenosine triphosphate (ATP) and decreased oxidative stress to values observed in livers which had never been preserved nor re-perfused. This points towards a potential use of silybin in liver transplantation surgery (Ligeret et al 2008).

Following silymarin treatment of liver fibrosis induced by carbon tetrachloride in rats, elevated levels of aspartate aminotransferase (AST), alanine aminotransferase (ALT) and alkaline phosphatase (ALP) were decreased (Tsai et al 2008).

Antioxidant effect

Several constituents found in St Mary's thistle have demonstrated antioxidant and free radical scavenging activity in a variety of models. Silymarin exerts both a direct and an indirect free radical scavenging activity, increasing the redox state and total glutathione content of the liver, intestine and stomach in vivo (Gonzalez-Correa et al 2002, Hagymasi et al 2002, Liu et al 2001, Valenzuela et al 1989). Other studies have shown that silymarin regenerates antioxidant enzymes (Kiruthiga et al 2007), but to a lesser extent than ascorbic acid (Das & Vasudevan 2006). The observed antioxidant activity of silymarin is dose dependent (Asghar & Masood 2008). Silybin fully alleviates the rise in metabolic flow driven radical oxygen species (ROS) formation in concentrations as low as 10 μm, which is particularly important in pathological conditions where the generation of mitochondrial ROS is significantly increased (Detaille et al 2008). Moreover, antioxidant and free radical scavenging activities inhibited the generation of oxidised LDL and subsequent scavenger receptor-dependent monocyte adhesion (Wallace et al 2008). Silydianin has shown to activate caspase-3, to stabilise cell membranes and to scavenge free radicals (Zielinska-Przyjemska & Wiktorowicz 2006).

Anti-inflammatory

The anti-inflammatory activity of silymarin is due to several different mechanisms, such as antioxidant and membrane-stabilising effects, and inhibition

of the production or release of inflammatory mediators, such as arachidonic acid metabolites. Inhibitory activity on lipo-oxygenase, cyclo-oxygenase (COX) and prostaglandin (PG) synthetase has been demonstrated in several in vitro assays and animal studies (Alarcon de la Lastra et al 1992, Dehmlow et al 1996, Fiebrich & Koch 1979, Rui et al 1990, Zhao et al 1999). Furthermore, silymarin inhibits NF-kappaB signalling and suppresses tumour necrosis factor (TNF)-alpha, nitric oxide synthase (iNOS) and interleukin (IL)-1 (Agarwal et al 2006, Polyak et al 2007).

Brain- and cardioprotective effect

Silymarin has been shown to reduce sepsis-induced lung and brain injury, partially through its antioxidant effects, inhibition of neutrophil infiltration and regulation of inflammatory mediator release (Nencini et al 2007, Toklu et al 2008).

Furthermore, silybin has protected rat cardiac myocytes against isoproterenol-induced injury by restarting mitochondrial function and upregulating the expression of SIRT1 and anti-apoptotic Bcl-2 family proteins (Zhou et al 2006a, 2006b). A subsequent study by the same authors found that the cardiac myocytes were protected against isoproterenol-induced DNA damage by silybin via the caspase-3 pathway and downregulation of p53 phosphorylation (Zhou et al 2006a, 2006b). Thus, silybin seems to exert anti-apoptotic (cell death preventing) properties.

Nephroprotective effect

In vitro experiments with kidney cells damaged by paracetamol, cisplatin or vincristin demonstrate that administration of silybin before or after the chemical-induced injury can lessen or avoid the nephrotoxic effects (Sonnenbichler et al 1999). Animal studies have confirmed the nephroprotective effect for cisplatin-induced injury (Karimi et al 2005). In one study, the effects of cisplatin on glomerular and proximal tubular function as well as proximal tubular morphology were totally or partly ameliorated by silybin (Gaedeke et al 1996). In an in vivo study, silymarin significantly decreased gentamicin-induced nephrotoxicity when used as a single agent and when used in combination with vitamin E in comparison to the placebo group. Serum creatinine concentrations, but not urea concentrations, were significantly lower (Varzi et al 2007).

Gastroprotective effect

St Mary's thistle extract produces a dose-dependent antiulcerogenic activity against indomethacin-induced ulcers, which can be histologically confirmed, according to research with test animals (Khayyal et al 2001). This is associated with reduced acid output, increased mucin secretion, increased PGE_2 release and decreased leukotriene release. Experiments with silymarin have found it to be effective in the prevention of gastric ulceration induced by cold-restraint stress in rats (Alarcon de la Lastra et al 1992) and post-ischaemic gastric mucosal injury (Alarcon de la Lastra et al 1995).

In combination

A herbal formulation known as STW 5, containing extracts of milk thistle fruit and eight other herbs (bitter candy tuft, lemon balm leaf, chamomile flower, caraway fruit, peppermint leaf, licorice root, angelica root and greater celandine) produced antiulcerogenic activity against indometacin-induced gastric ulcers in rats as well as antisecretory and cytoprotective activities (Khayyal et al 2001). In a newer study, it was shown that STW 5 lowered the gastric acidity as effectively as commercial antacid preparations (i.e. Rennie, Talcid, Maaloxan), prevented secondary hyperacidity more effectively and, additionally, inhibited serum gastrin levels in rats (Khayyal et al 2006).

Antidiabetic effect

Silybin lowered glucose production from various gluconeogenic substrates in perifused rat hepatocytes. Silybin also reduced glycolysis from carbohydrates in a cell perifusion system in a dose-dependent manner via an inhibitory effect on pyruvate kinase activity. Furthermore, a dramatic effect upon oxidative phosphorylation was shown and illustrated by a decrease in ATP-to-adenosine diphosphate (ADP) ratio and an increase in lactate-to-pyruvate ratio (Detaille et al 2008).

Antiviral effect

In an in vitro study, a standardised St Mary's thistle extract (MK-001) and other commercial St Mary's thistle preparations combined with interferon-alpha inhibited hepatitis C virus (HCV) replication more than when interferon-alpha was given alone. Silybin A and B as well as isosilybin A and B displayed the strongest effects (Polyak et al 2007). Interestingly, milk thistle has no direct antiviral activity, but rather has protective effects in the inflammatory response to HCV, thereby supporting antiviral treatment in this disease (Torres et al 2004).

Mast-cell stabilisation

Silybin has shown mast-cell-stabilisation activity in vivo (Lecomte 1975), which was confirmed some years later and found to be dose dependent (Fantozzi et al 1986). Silymarin has been shown to exert protective effects in the early phase of asthma, most likely due to its influence on histamine release (Breschi et al 2002).

Antifibrotic

Silymarin reduces markers for collagen accumulation in the liver and exerts antifibrotic activity, according to an animal model of liver fibrosis (Boigk et al 1997).

Antitumour effects

In a variety of in vitro and in vivo research, silymarin and silybin have demonstrated both cancer-preventive and anticancer activities, although the antitumour activity is less than for some other herbals such as Wild Yam, echinacea, cayenne, and astragalus (Mazzio & Soliman 2008). In addition, a research shows antimetastatic activity in animal studies (Raina et al 2008, Ramasamy & Agarwal 2008).

Strong anticancer effects have been identified in human skin, cervical, prostate, bladder, colon, breast carcinoma, hepatocellular carcinoma, laryngeal squamous carcinoma cells (Bang et al 2008, Hogan et al 2007, Post-White et al 2007, Varghese et al 2005, Vinh et al 2002, Zi & Agarwal 1999, Zi et al 1998a, 1998b, Zhao et al 1999, Zhu et al 2001). One study reported that 0.05–0.1% of silybin in the diet did not show any effects on pulmonary adenoma formation and growth in mice (Yan et al 2005), but inhibited lung tumour angiogenesis in mice (Singh et al 2006).

Two studies involving the use of topical silymarin in hairless mice before chemical carcinogenesis and photocarcinogenesis have shown a protective effect that resulted in a statistically significant decrease in tumour incidence, tumour multiplicity and tumour volume per mouse in the treated groups (Wright et al 2006). Furthermore, this chemopreventive effect was found to be dose dependent in one of the studies, in which the topical application ranged from 3 to 12 mg per mouse, with the 12-mg application conferring the most protection.

It appears that several mechanisms are responsible for the chemopreventive and anticancer effects, besides an antioxidant effect (Agarwal et al 2006, Gazak et al 2007). In vivo research has demonstrated chemopreventive effects for silymarin, by inhibiting endogenous tumour promoter TNF-alpha (Zi et al 1997). Anti-angiogenic activity has also been observed, and is likely to be involved (Jiang et al 2000). For example, in a mouse prostate adenocarcinoma model, silybin showed antiproliferative effects and inhibited angiogenesis (Raina et al 2008). In human colon cancer cells, milk thistle displayed antiproliferative effects through cell-cycle arrest via inhibition of cyclin-dependent kinase promoter activity (Hogan et al 2007). Investigating prostate carcinoma cells, researchers found that p21 and p27 induction played a role in silybin-mediated cell-cycle arrest (Roy et al 2007).

Research also shows that silymarin inhibits the increase in mast-cell density in a developing neoplasm and downregulates the expression of matrix metalloproteinases 2 and 9, which are involved in invasion and angiogenesis and therefore required for metastasising (Lee et al 2007, Ramakrishnan et al 2008). Lee et al found that silybin suppresses PMA-induced MMP-9 expression by blocking the AP-1 activation via MAPK signalling pathways in MCF-7 human breast carcinoma cells (Lee et al 2007). In addition to a decreased expression of matrix metalloproteinases, mesenchymal markers snail-1, and fibronectin in the prostatic tissue and retention of epithelial characteristics may also be associated with a decrease of metastasis (Raina et al 2008). Silybin was found to exert a dose- and time-dependent inhibitory effect on the viability, motility and adhesion of highly metastatic prostate cancer cells (Mokhtari et al 2008).

In vitro studies have shown that silymarin possesses high cancer-preventive effects in different mouse skin carcinogenesis models. Silymarin provides substantial protection against different stages of UVB-induced carcinogenesis, via its strong antioxidant properties (Katiyar et al 1997, Svobodova et al 2007) and a selective action on NF-kappaB activation (Saliou et al 1999). Topical application of silymarin provided significant protection against different stages of UVB-induced skin carcinogenesis in mouse skin tumourigenesis models (Ahmad et al 1998, Lahiri-Chatterjee et al 1999). Investigations have demonstrated that silymarin inhibited UV-induced oxidative stress through targeting infiltrating the CD11b+ cell type in the skin (Katiyar et al 2008). An earlier study found silybin has a protective effect against UV radiation in human keratinocytes by inactivation of caspase-8 after direct downregulation of Fas-associating protein with death domain (Hoh et al 2006). Similarly, in human malignant melanoma cells silymarin exaggerated the apoptotic effect of anti-Fas agonistic antibody CH11 (Li et al 2007). Topical and systemic silymarin caused an upregulation of tumour suppressor genes p53 and p21CIP1 (Saller et al 2007). It has also been shown that systematic and topical application of silymarin was effective against burn-induced oxidative damage and morphological alterations in rat skin (Toklu et al 2007).

Contradictory results exist for the effects of milk thistle on breast cancer cells. In rats, silymarin modestly increased the number of mammary tumours (Malewicz et al 2006). Also, treatment of MCF-7 cells with serum-achievable concentrations of silymarin in the rodent models stimulated their growth, partially through an oestrogen-like activity (Malewicz et al 2006). In contrast in tumoural mammary glands in transgenic mice, tumour growth was inhibited by silymarin (Provinciali et al 2007). However, in a multiple mammary adenocarcinoma mouse model, silybin or silipide did not promote or interfere with tumour development (Verschoyle et al 2008).

OTHER ACTIONS

Cholesterol lowering

Cholesterol reduction has been demonstrated for silymarin in two studies of rats fed a high-cholesterol diet (Krecman et al 1998, Sobolova et al 2006). Although the mechanism of action is unknown, it has been suggested that inhibition of HMG-CoA reductase (Skottova & Krecman 1998a) and inhibition of cholesterol absorption from dietary sources (Sobolova et al 2006) are involved.

Considering that the herb also contains phytosterols, these too may play a role in cholesterol reduction.

Neuroprotective

Silymarin demonstrated neuroprotective activity according to preliminary research. A study by Wang et al (2002) demonstrated that silymarin could effectively protect dopaminergic neurons against lipopolysaccharide-induced neurotoxicity by inhibiting activation of the microglia that represent resident macrophage-like population of brain cells acting in host defence and tissue repair in the CNS. Silymarin induced an increase of reduced glutathione and ascorbic acid levels and superoxide

dismutase activity in the brain of treated rats (200 mg/kg/day PO) for 3 days, showing a protective effect on antioxidant defence systems.

Pharmacokinetics

Silybin undergoes fast absorption and elimination and has dose-related pharmacokinetics in the dose ranges of 10–50 mg/kg. The authors suggest active hepatobilliary excretion partially inhibited by P-gp (Wu et al 2008). Silybin administration in rats gave greater bile levels of unconjugated silybin and total silybin than in plasma and the oral bioavailability of silybin in rats was estimated to be 0.73% (Wu et al 2007). Silybin can be absorbed in the whole intestine. The uptake of silybin was similar at 190 and 300 microgram/mL (Luan & Zhao 2006).

Following oral administration, silymarin is quickly metabolised. It undergoes phase I and phase II metabolism, especially phase II conjugation reactions, forming glucuronides detectable in human plasma. It undergoes multiple conjugation reactions and is primarily excreted into bile and urine (Pradhan & Girish 2006, Venkataramanan et al 2006, Wen et al 2008, Wu et al 2009). Silymarin has limited effect on the pharmacokinetics of several drugs in vivo, as only a few reports of silymarin decreasing the activity of cytochrome P-450 (CYPs) enzymes and reducing P-glycoprotein (P-gp) transport exist.

Effects on CYP450 enzymes

Conflicting results from different studies make it difficult to determine what effect silymarin has on CYP450 enzymes. Early in vitro studies showed some evidence of CYP3A4 inhibition and, possibly, inhibition of other CYP enzymes (Venkataramanan et al 2000, Zuber et al 2002). Results published in 2002 suggest that the flavolignans silybin, silydianin and silycristin display a dose-dependent inhibition of CYP3A4, CYP2E1 and CYP2D6 (Zuber et al 2002). An in vitro study confirmed the downregulation of CYP3A4 expression by silybin (Budzinski et al 2007).

Three other in vitro studies could not confirm inhibitory effects for silymarin on CYP2E1, with one study actually reporting induction activity (Etheridge et al 2007, Kim et al 1997, Miguez et al 1994). Moreover, another study did not confirm the effects reported for CYP2D6, but showed that milk thistle extract can inhibit CYP2C8 at 10 μm (Etheridge et al 2007).

However, it seems that reported in vitro effects have no clinical relevance in vivo. For example, in 2003, a crossover study of healthy volunteers found that silymarin (160 mg three times daily) had no apparent effect on indinavir plasma concentrations, suggesting no significant effect on CYP3A4 in humans (DiCenzo et al 2003). A subsequent clinical study found no evidence of an interaction between St Mary's thistle and indinavir when administered in commonly used therapeutic doses (DiCenzo et al 2003). Three further clinical studies found milk thistle extract had no significant effect on the pharmacokinetics of CYP3A4 substrates (irinotecan, midazolam, nifedipine).

One study of six cancer patients tested the use of milk thistle (400 mg daily) for 4 days and 12 days, finding no effect on irinotecan clearance and extent of glucuronidation (van Erp et al 2005). Similarly, in a study with healthy volunteers receiving 900 mg of standardised milk thistle extract for 14 days, no effects on the pharmacokinetics of midazolam were observed (Gurley et al 2006a, 2006b). In another human study, silymarin had no significant effect on the metabolism of orally administered nifedipine, but a possible decrease in the absorption rate of nifedipine was noted (Fuhr et al 2007).

Similarly, clinical studies have found no significant effects for milk thistle extract on CYP2D6 (Gurley et al 2008) or CYP2C9 for silmarin (210 mg/day) taken over 28 days (Leber & Knauff 1976).

Effects on P-glycoprotein

An in vitro study identified that silymarin inhibited P-glycoprotein (P-gp) ATPase activity in such a way as to suggest direct interaction with P-gp substrate binding (Zhang & Morris 2003). However, Gurley et al concluded that milk thistle is not a potent P-gp modulator, following their study where milk thistle extracts did not show any effect on digoxin pharmacokinetics in comparison to rifampin and clarithromycin (Gurley et al 2006a, 2006b).

Effects on UDP glucuronosyltransferase

No in vitro effects on UDP glucuronosyltransferase isoform 1A1 were reported (van Erp et al 2005).

CLINICAL USE

Dyspepsia

Although St Mary's thistle has been most commonly investigated for its effects as a hepatoprotective agent, it is commonly used to treat dyspeptic complaints, such as loss of appetite, poor digestion and upper gastrointestinal discomfort. Animal studies have identified a dose-dependent increase in bile flow and bile salt secretion for silymarin, achieved by stimulating the synthesis of bile salts (Crocenzi et al 2000). Silymarin has been found to impact on bile salt synthesis, bile secretion, biotransformation of cholestatic compounds and changes in transported expression and activity (Crocenzi and Roma, 2006).

Commission E approves the use of crude milk thistle preparations for dyspeptic complaints (Blumenthal et al 2000).

Toxic liver damage

Mushroom poisoning (*Amanita phalloides*)

One of the best-documented uses of milk thistle is in the treatment of poisoning by the mushroom *Amanita phalloides* (death cap). Nausea, vomiting, abdominal cramps and severe diarrhoea usually occur 8–12 h after ingestion, with extensive hepatic necrosis occurring 1–2 days later. A mortality rate of 20–30% has been observed but can be as high as 50% in children under 10 years of age (Floersheim et al 1982). Several clinical studies have shown silybin (20–50 mg/kg/day IV) to protect against hepatotoxicity when administered within 48 h.

One report of pooled data from 452 case reports of *A. phalloides* poisoning showed a highly significant difference in mortality in favour of silybin (Saller et al 2001).

Environmental toxins and drugs

In animals, milk thistle reduces acute liver injury caused by paracetamol (Ali et al 2001, Muriel et al 1992), carbon tetrachloride (Favari & Perez-Alvarez 1997, Letteron et al 1990), radiation (Hakova & Misurova 1996, Kropacova et al 1998), iron overload (Masini et al 2000, Pietrangelo et al 1995), phenylhydrazine (Valenzuela & Guerra 1985) and D-galactosamine (Tyutyulkova et al 1981, 1983).

One randomised, double-blind study involving 222 patients showed that silymarin improves the tolerability of tacrine without altering the drug's cognitive effects (Allain et al 1999). Two other clinical trials have documented the effectiveness of silymarin in improving or preventing hepatotoxicity from chronic administration of phenothiazines or butyrophenone (Anon 1989).

Hepatocyte repair

The effects of a commercial silymarin product (Legalon 120 mg three times daily) on liver function tests and liver histology were studied in 36 patients with chronic alcoholic liver disease in a 6-month, double-blind clinical trial (Feher et al 1989). Treatment not only produced significant improvements in liver function test results, but also positive effects on histology, while these parameters remained unchanged in the placebo group. Salmi and Sarna (1982) found similar results in a randomised controlled trial (RCT) of 106 patients with liver disease. After just 4 weeks' treatment, histological changes began to normalise significantly more often in the treated group than in controls.

A review concluded that the clinical evidence for a therapeutic effect in toxic liver disease is scarce, but that it is reasonable to employ silymarin as adjunct therapy in the treatment of *Amanita phalloides* poisoning (Saller et al 2008). Commission E approves the use of standardised St Mary's thistle extracts (70–80% silymarin content) for toxic liver damage (Blumenthal et al 2000).

Supportive treatment in chronic liver diseases

Numerous clinical trials have been conducted with St Mary's thistle preparations in various chronic liver diseases. The most studied treatments are Legalon (Madaus Corporation, Cologne, Germany) and Silipide (Inverni Della Beffa Research and Development Laboratories, Milan, Italy), designed to improve oral absorption of silymarin.

A 1998 clinical review of St Mary's thistle concluded that it may be effective in improving the clinical courses of both acute and chronic viral, drug-induced, toxin-induced and alcoholic hepatitis (Flora et al 1998). A systematic review of efficacy for St Mary's thistle in chronic liver diseases stated that data are still too limited to detect a substantial benefit on mortality or recommend the herb in liver disease (Jacobs et al 2002).

> ***Clinical note — Hepatic fibrosis***
> Hepatic fibrosis is a pathological wound-healing process that occurs when the liver is injured chronically, such as in chronic alcohol abuse. The oxidative metabolite of ethanol, acetaldehyde, often in conjunction with viral or metabolic liver disease, is implicated as the major cause for liver fibrogenesis, which ultimately leads to cirrhosis (Schuppan et al 1995). Antifibrotic agents, which interrupt the continuous process of wound healing in the liver, are being investigated as strategies to prevent or reverse liver cirrhosis.

Twelve clinical studies were located in which researchers have attempted to clarify the role of St Mary's thistle in the treatment of various liver diseases (Angulo et al 2000, Benda et al 1980, Buzzelli et al 1993, Ferenci et al 1989, Loguercio et al 2007, Lucena et al 2002, Magliulo et al 1978, Par et al 2000, Pares et al 1998, Salmi & Sarna 1982, Trinchet et al 1989, Velussi et al 1997). Much of the research focuses on the different forms of hepatitis and alcoholic liver cirrhosis with doses ranging from 100 to 300 mg three times daily, usually given in a standardised extract of 70–80% silymarin. Overall, results have been mixed, with nine trials showing generally positive results and three negative, suggesting that milk thistle is effective in only some forms of liver disease.

Alcoholic liver disease

A 2005 Cochrane review of 13 randomised clinical trials and a 2007 Cochrane review of 18 randomised clinical trials assessed milk thistle in 915 and 1088 patients, respectively, looking at its effect in alcoholic and/or hepatitis B or C virus liver diseases (Rambaldi et al 2007, 2005). The authors stated in both reviews that the methodological quality of the trials was low and that milk thistle versus placebo or no intervention had no significant effect on complications of liver disease or liver histology, and that milk thistle was not associated with a significantly increased risk of adverse events. In comparison to the 2005 review, which concluded that liver-related mortality was significantly reduced by milk thistle in patients with alcoholic liver disease, the 2007 review found that liver-related mortality was significantly reduced by milk thistle in all trials, but not in high-quality trials (Rambaldi et al 2007, 2005). Another review supports this view (Bergheim et al 2005).

Acute viral hepatitis

Several studies have investigated the use of milk thistle in this disease, reporting beneficial effects on serological outcomes (Bode et al 1977, Magliulo et al 1978, Tkacz & Dworniak 1983). However, several studies were not clearly blinded and further research is required to determine whether St Mary's thistle can provide significant benefits in this population.

Hepatitis C infection

A 2003 systematic review of medicinal herbs for HCV infection concluded that compared with placebo, none of the herbs showed effects on HCV RNA or liver enzyme, except for the constituent silybin, which showed a significant reduction of serum AST and gamma-glutamyltranspeptidase levels in one trial (Liu et al 2003). In a 4-week randomised, controlled clinical trial (n = 34) using 160 mg of milk thistle three times a day, AST, ALT and viral load values decreased from baseline levels after 4 weeks although the effect was not significant. In comparison, values for ALT and viral load showed a significant increase in the control group over the same period. When treatment and control groups were then compared, a significant difference was observed for ALT and AST, but not for viral load (Torres et al 2004). Similarly, a 2005 review concluded that silymarin decreases serum AST and ALT levels, but does not seem to affect viral load or liver histology (Mayer et al 2005). A newer randomised, double-blind, placebo-controlled, crossover study (n = 24) where subjects received 12 weeks treatment with 600 or 1200 mg milk thistle daily, viral load, ALT levels and quality of life scores (short-form (SF)-36) were not significantly different to placebo (Gordon et al 2006). As part of the hepatitis C Antiviral Long-Term Treatment Against Cirrhosis (HALT-C) trial (n = 1145 participants), involving people with advanced chronic hepatitis C, non-responders to prior antiviral therapy continued taking pegylated interferon treatment with the addition of oral silymarin therapy; however, no changes to ALT and viral load were observed with adjunctive herbal treatment. Silymarin therapy did significantly lower liver-related symptoms and improved QOL parameters such as fatigue, nausea, liver pain, anorexia, muscle and joint pain, as well as general health (Seeff et al 2008). Intravenously administered silymarin produced a substantial antiviral effect against HCV in pedigreed non-responders to full-dose pegylated interferon/ribavirin and was well tolerated (Ferenci et al 2008).

Surprisingly, a review found no evidence for a beneficial effect of silymarin on the progression of viral hepatitis, especially hepatitis C (Saller et al 2008).

Commission E approves the use of standardised St Mary's thistle extracts (70–80% silymarin content) as supportive treatment in chronic inflammatory liver disease and hepatic cirrhosis (Blumenthal et al 2000). A review concluded that silymarin 'is reasonable' to be employed as an adjunct therapy for alcoholic and grade Child 'A' liver cirrhosis (Saller et al 2008).

Diabetes

Silymarin has also been investigated in diabetic patients with cirrhosis. Velussi et al (1997) investigated whether long-term treatment with silymarin is effective in reducing lipoperoxidation and insulin resistance in diabetic patients with cirrhosis. The 6-month open trial found that silymarin treatment had several benefits. After the first month's treatment, fasting glucose levels showed a progressive and significant decline that, interestingly, did not lead to an increase in the frequency of hypoglycaemic episodes. Other observations revealed decreased glucosuria and levels of glycosylated haemoglobin also decreased significantly, indicating an overall improvement in glucose control. The dose used was 600 mg/day silymarin.

OTHER USES

Traditionally, the seeds have been used to treat jaundice, hepatitis, haemorrhoids and psoriasis, as a tonic for nursing mothers, and as a general 'liver cleansing' agent.

Hypercholesterolaemia

In clinical practice, it is not unusual to find treatment with St Mary's thistle at the higher end of the dose range results in cholesterol lowering effects. Several in vivo studies confirm that St Mary's thistle increases LDL cholesterol clearance and raises HDL cholesterol levels; however, only one clinical trial is available to determine whether the effect is clinically significant (Krecman et al 1998, Skottova & Krecman 1998b, Somogyi et al 1989). An open trial involving 14 subjects with type 2 hyperlipidaemia found that treatment with silymarin (420 mg/day) slightly reduced total cholesterol and HDL cholesterol levels (Somogyi et al 1989).

Cancer prevention and treatment

In vivo research suggests that silymarin and/or its major active constituent silibinin could be an effective agent for prevention and/or supportive treatment of human skin cancer (Singh et al 2002, Zhao et al 2000). Topical application of silymarin provided significant protection against different stages of UVB-induced skin carcinogenesis in mouse skin tumourigenesis models (Ahmad et al 1998, Lahiri-Chatterjee et al 1999).

Chemotherapy support

The role of St Mary's thistle as adjunctive therapy in a range of cancer treatments has received much interest in the past few years. Silybin appears to have nephroprotective activity effective against cisplatin and vincristine toxicity in vitro (Sonnenbichler et al 1999). Protection against cisplatin nephrotoxicity has been confirmed in vivo by Gaedeke et al (1996), who showed that the adverse effects of cisplatin on creatinine clearance and proteinuria were totally prevented by silybin pretreatment. Bokemeyer et al (1996) confirmed the nephroprotection afforded by silybin in a rat animal model and observed that it did not alter the clinical efficacy of cisplatin. According to an in vivo study by Karimi et al (2005), both silymarin and St Mary's thistle extract are also effective when given as pretreatment before cisplatin.

In vitro and in vivo research has further shown that a combination of silybin with cisplatin produces a dose-dependent and statistically significant increase of drug activity, resulting in a potentiation of antitumour activity (Giacomelli et al 2002, Scambia et al 1996).

Clinical note — Cisplatin
Cisplatin is one of the most active cytotoxic agents in the treatment of testicular cancer, but its clinical use is associated with side effects, such as severe nausea, ototoxicity, neurotoxicity and nephrotoxicity (Giacomelli et al 2002). It is also used in the treatment of head and neck, gastrointestinal, cervical, lung and bladder cancer.

Diabetes
A 4-month randomised, double-blind, placebo-controlled trial in 51 type 2 diabetes patients receiving silymarin (200 mg three times daily) as an adjunct treatment to their conventional therapy showed a significant decrease in HbA_{1c}, fasting blood glucose, total cholesterol, LDL and triglyceride levels compared with placebo as well as with values at the beginning of the study in each group (Huseini et al 2006).

DOSAGE RANGE
- The average daily recommended dose is 12–15 g (practitioners have used doses as high as 18 g/day) of milk thistle seed, usually in divided doses (equivalent to 200–400 mg silymarin) (WHO 2003).
- Liquid extract (1:1): 4–9 mL/day (Mills & Bone 2000).
- Liquid extract (1:2): 30–60 mL/week.
- Silybin-phytosome: 13 g daily (Flaig et al 2007)

TOXICITY

Extremely low
Toxicity studies in rats and mice have shown that silymarin, even at daily doses as high as 2500–5000 mg/kg, produced no adverse toxic effects (Madaus 1989). In a 12-month study in rats and dogs given up to 2500 mg/day, no signs of toxicity were seen. Milk thistle products with a standardised content of silymarin (70–80%) were found to be safe for up to 41 months of usage (Francine 2005).

ADVERSE REACTIONS
Milk thistle is considered safe and well tolerated when taken within the recommended dose range (Post-White et al 2007). A review of studies involving more than 7000 participants identified three cases of serious adverse reactions (two anaphylaxis and one gastroenteritis symptoms) (Jacobs et al 2002). In one clinical trial, patients with colorectal adenocarcinoma who received silipide (silybin with phosphatidylcholine) at dosages of 360, 720 or 1440 mg daily for 7 days found the administration of silipide to be safe (Hoh et al 2006). Another clinical trial (n = 13) reported hyperbilirubinaemia in 9/13 patients and increased ALT in 1/13 patients using silybin-phytosome (Flaig et al 2007), whereas all other trials reported only rare adverse events (Gordon et al 2006, Rainone 2005, Torres et al 2004), mostly gastrointestinal symptoms, even for intravenously administered silymarin (Ferenci et al 2008). Reviews concluded that silymarin has an excellent safety profile (Dryden et al 2006, Rainone 2005, Sagar 2007).

Overall, adverse effect frequency was the same as for placebo and had a low frequency, ranging from 2% to 10% in controlled trials. In practice, loose bowels have been reported, although the reaction is considered rare.

SIGNIFICANT INTERACTIONS
Although some in vitro evidence indicates that effects on cytochrome P-450 (CYPs) enzymes and P-glycoprotein (P-gp) transport exist, several in vivo studies report limited or no effects on the pharmacokinetics of several drugs (Wu et al 2009). Importantly, clinical trials indicate no significant changes in the pharmacokinetic profiles of several CYP3A4 substrates (Fuhr et al 2007, Gurley et al 2006a, 2006b, van Erp et al 2005), P-glycoprotein (Gurley et al 2006a, 2006b), CYP2D6 (Gurley et al 2008) or CYP2C9 (Leber & Knauff 1976).

Cisplatin
Preliminary research has shown this combination may reduce toxic effects, yet enhance antitumour activity — adjunctive use may be beneficial when used under professional supervision.

Doxorubicin
Silymarin reduces cardiotoxicity and possibly chemosensitises resistant cells to anthracyclines — adjunctive use may be beneficial when used under professional supervision.

Hepatotoxic substances
General hepatoprotective effects reported for silymarin — adjunctive use may be beneficial when used under professional supervision.

CONTRAINDICATIONS AND PRECAUTIONS
Contraindicated in people with known allergy to the Asteraceae (Compositae) family of plants. One case of exacerbation of haemochromatosis due to ingestion of milk thistle has been reported (Whittington 2007); however, the association between herbal intake and outcome reported is unlikely (Kidd 2008).

PREGNANCY USE
Insufficient reliable information is available to determine safety in pregnancy.

PATIENTS' FAQs
What will this herb do for me?
St Mary's thistle may improve digestion, particularly of fatty foods, and afford protection against the toxic effects of a number of drugs and environmental poisons. It is also used as supportive treatment in chronic liver diseases and high-cholesterol states.
When will it start to work?
This varies, depending on the indication.
Are there any safety issues?
St Mary's thistle is considered a very safe and well-tolerated herb.

ADDITIONAL READING
For the interested reader, a comprehensive review exists summarising most clinical trials on the safety and efficacy of milk thistle (Tamayo & Diamond

2007). Two other comprehensive reviews summarise milk thistle's mechanism of action (Comelli et al 2007) and clinical application in oncology (Greenlee et al 2007a, 2007b).

PRACTICE POINTS/PATIENT COUNSELLING

- St Mary's thistle has hepatoprotective activity and has been shown to reduce the hepatotoxic effects of a variety of environmental toxins and medicines, such as paracetamol, erythromycin, carbon tetrachloride and death cap mushrooms.
- It has direct and indirect antioxidant activities, accelerates the regeneration of hepatocytes after liver damage, has significant gastroprotective and nephroprotective activities, anti-inflammatory and antihistamine activities, according to in vitro and animal studies.
- Numerous clinical studies have investigated its effects in a variety of liver diseases, although reviews still conclude that current data are insufficient to routinely recommend the herb in chronic liver diseases.
- In clinical practice, it is used to treat dyspepsia, toxic liver damage, as supportive therapy in chronic liver diseases and hypercholesterolaemia.
- Preliminary evidence suggests a possible role as adjunctive therapy with cisplatin and as a skin cancer preventative agent when applied topically.

Saw palmetto

HISTORICAL NOTE Saw palmetto was used traditionally as a treatment for urogenital irritations, impotence and male infertility, among other conditions, and was described by the American Eclectic physicians as the 'old man's friend'. Between 1906 and 1917 saw palmetto was listed in the US Pharmacopoeia and between 1926 and 1950 it was in the National Formulary as a treatment for urogenital ailments; however, it fell out of favour for several decades as pharmaceutical medicines came to the forefront of mainstream medicine. Not so in Europe where, in the 1960s, French researchers began to chemically analyse the saw palmetto berry, and a breakthrough lipophilic preparation was eventually developed and subjected to countless clinical trials.

COMMON NAME
Serenoa or saw palmetto

OTHER NAMES
American dwarf palm tree, cabbage palm, dwarf palmetto, fan palm, sabal fructus, sabal, serenoa

BOTANICAL NAME/FAMILY
Sabal serrulata, Serenoa repens (family Arecaceae or Palmaceae)

PLANT PART USED
Dried ripe fruit

CHEMICAL COMPONENTS
An ethanol extract of the berry contains free fatty acids rich in shorter chain-length fatty acids, such as capric, caprylic, lauric and myristic acids (Nemecz 2003). Palmitic, stearic, oleic, linoleic and linolenic acids are also present in the extract. There are also lesser amounts of phytosterols (such as beta-sitosterol, stigmasterol, ampesterol and cycloartenol), aliphatic alcohols and polyprenic compounds. The lipophilic extract is used medicinally.

MAIN ACTIONS
The mechanism of action is not fully elucidated; however, it appears that several mechanisms are at work.

Inhibition of 5-alpha reductase
In different cell systems, the lipid-sterolic extract acts as a non-competitive inhibitor of both type 1 and type 2 5-alpha reductase activity, thereby preventing the conversion of testosterone to dihydrotestosterone (Bayne et al 2000, Raynaud et al 2002, Sultan et al 1984). However, it is currently unclear whether the effect is apparent in humans, as contradictory evidence exists. Raynaud et al (2002) explained that the discrepancies found by different authors were due to different experimental conditions and selectivity for fatty acids, as only specific aliphatic unsaturated fatty acids have been shown to inhibit 5-alpha reductase activity.

One study that analysed and compared benign prostatic hyperplasia (BPH) samples taken from both untreated and treated subjects (320 mg saw palmetto extract taken for 3 months) found that local levels of testosterone were raised, whereas dihydrotestosterone levels were reduced, suggestive of local 5-alpha reductase inhibition (Di Silverio et al 1998). An earlier, short-term study found that a dose of 160 mg of a liposterolic extract (Permixon) produced no changes to serum dihydrotestosterone levels, whereas finasteride 5 mg induced a significant reduction (Strauch et al 1994). Since prostate levels were untested in this study, it is not known whether a local effect occurred, even though serum levels remained unchanged.

Unlike other 5-alpha reductase inhibitors, there is no interference with the cell's capacity to secrete prostate-specific antigens because it does not affect the transcription of the gene for prostate-specific antigen (PSA), as demonstrated both in vitro and in vivo (Maccagnano et al 2006). Although having an obvious clinical advantage with regard to PSA screening for prostate cancer, this also suggests that 5-alpha reductase inhibition is not a major activity.

Inhibits binding of dihydrotestosterone and testosterone to androgen receptors
Saw palmetto reduces receptor binding of dihydrotestosterone and testosterone by an average of 41%, as tested in 11 different tissue specimens from BPH patients (el Sheikh et al 1988). In 2003, results from two animal studies showed that saw palmetto (whole berry and extract) influenced prostatic hyperplasia via effects on androgen metabolism (Talpur et al 2003).

Inhibits prolactin
In vivo research has identified not only an inhibitory effect on androgens, but also on the trophic effect of prolactin in the rat prostate (Van Coppenolle et al 2000). The inhibitory effect on prolactin activity appears to be due to inhibition of several steps in prolactin receptor signal transduction, according to one animal model (Vacher et al 1995).

Anti-inflammatory
Saw palmetto is a dual inhibitor of the COX and 5-lipoxygenase pathways, according to in vitro research (Breu et al 1992, Paubert-Braquet et al 1997). More recently, decreased expression of COX-2 has been identified, providing a further explanation for the observed anti-inflammatory activity (Goldmann et al 2001).

Antispasmodic
Both the lipid and saponifiable fractions have demonstrated antispasmodic activity in several in vitro studies (WHO 2003).

Cytochromes

Saw palmetto failed to have a significant effect on CYP3A4 or CYP2D6 when tested in healthy individuals (Markowitz et al 2003).

Antiproliferative effects

In recent years, there has been interest in determining whether saw palmetto may have a role in prostate cancer, as an inhibitory activity has been observed in several test tube studies for prostatic cancer cell lines (Goldmann et al 2001, Ishii et al 2001).

OTHER ACTIONS

Although alpha-1 adrenoreceptor activity has been reported in vitro, a clinical study found no evidence of this activity (Goepel et al 1999, 2001). Saw palmetto does not affect platelet function in vivo (Beckert et al 2007).

Traditionally, saw palmetto is believed to act as a mild diuretic, urinary antiseptic and expectorant.

CLINICAL USE

The most studied saw palmetto preparation is a commercial product known as Permixon (Pierre Fabre Médicament, Castres, France), which is a liposterolic extract consisting of 80% free (e.g. 94 g/100 g extract) and 7% esterified fatty acids, as well as small amounts of sterols (beta-sitosterol, campesterol, stigmasterol, cycloartenol), and a minimum percentage of polyprenic compounds, arabinose, glucose, galactose, uronic acid and flavonoids.

BPH

Saw palmetto extracts are extremely popular in Europe where herbal preparations represent approximately one-third of total sales of all therapeutic agents sold for the treatment of BPH (Levin & Das 2000). In Germany, for instance, more than 30 different preparations containing saw palmetto are on the market. By far, most intensively studied product of this group is a n-hexane-liposterol-extract (Permixon® by Pierre Fabre Medicament, Boulogne, France), which is very popular in France and Italy. It is a complex mixture of free fatty acids and their esters, phytosterols, aliphatic alcohols and various polyprenic compounds (Madersbacher 2007).

Substantial evidence suggests that saw palmetto is an effective treatment for stages 1 and 2 of BPH. A 2002 Cochrane review assessing the results from 21 randomised trials involving 3139 men concluded that saw palmetto improves urinary scores, symptoms and urinary flow measures compared with placebo, with effects on symptoms scores and peak urine flow similar to the pharmaceutical drug finasteride (Wilt et al 2002). Additionally, its use is associated with fewer adverse effects compared with finasteride and, typically, symptomatic relief is reported more quickly.

In 2004, an updated meta-analysis of 14 randomised studies and three open-label studies was published (Boyle et al 2004). The analysis used data from 4280 patients derived from clinical studies that had used Permixon. Three randomised trials had a study period of 6 months or longer. Peak urinary flow rate and nocturia were the two common endpoints. Active treatment was associated with a mean reduction in the International Prostate Symptom Score (IPSS) of 4.78 (0.41). A significant improvement in peak flow rate and reduction in nocturia was also reported.

Since then, a double-blind study of 1 year of continuous treatment with saw palmetto extract (160 mg twice daily containing 92.1% total fatty acids) failed to produce significant differences compared with placebo for the American Urological Association Symptom Index, maximal urinary flow rate, prostate size, residual volume after voiding, quality of life or serum PSA levels (Bent et al 2006). It is unclear why this trial is contradictory to the general body of evidence that supports the use of saw palmetto in BPH. Bent et al suggest that previous studies had inadequate blinding; however, this seems unlikely for all studies. Another possible explanation relates to the differences in herbal extracts tested in different studies. Additionally, saw palmetto is most often used in cases of mild BPH, whereas this study included subjects with moderate-to-severe BPH, which may have contributed to the results observed; however, this is speculative.

In 2007, results of the European TRIUMPH study were published which provided support for the effectiveness of saw palmetto under real-world conditions, although it does not have benefits in everyone (Hutchison et al 2007). The study recorded treatment and outcomes of 2351 newly presenting men with lower urinary tract symptoms (LUTS) suggestive of BPH in six European countries over a 1-year follow-up period. At each visit, the clinician recorded the treatment, co-morbidities, complications and drugs prescribed, and the patient completed an IPSS questionnaire. The results were analysed using change in IPSS as the primary outcome measure. The efficacy of the three classes of drug (alpha-blockers, 5-alpha reductase and phytotherapy) was investigated by randomly matching each patient receiving only one class of drug over the study period to a watch-and-wait case on age at diagnosis (±2 years) and initial IPSS (±2 IPSS points). Based on this evaluation, authors concluded that significant improvements were seen in 43% of patients taking phytotherapy with *Serenoa repens* or *Pygeum africanum*. Saw palmetto produced a significant improvement in symptoms compared to untreated men ($P = 0.0003$). The best effects were seen with tamsulosin, which was also the most prescribed drug.

Positive results were obtained by Shi et al (2008) where treatment with Prostataplex™ (2 caps/day) significantly increased maximum urinary flow rate compared to placebo under double-blind test conditions. The 12-week study of 92 Chinese men (49–75 years) with lower urinary tract symptoms associated with BPH also found that active treatment significantly reduced relative urinary resistance. Interestingly, no significant difference in mean prostate volume or IPSS was found between the two groups; however, 18 of 46 patients (39.1%) in the treatment group showed an

IPSS improvement (decrease of three or greater) after intervention, whereas only 1 of 46 (2.2%) in the control group showed an IPPS improvement ($P < 0.001$).

Comparisons with alpha-adrenoreceptor antagonists

Although several comparative trials have been undertaken with finasteride, only a few have compared it with alpha-adrenoreceptor antagonist drugs, which are also commonly used in BPH (Adriazola et al 1992, Debruyne et al 2002). A large, randomised, double-blind study involving 811 men with symptomatic BPH, who were recruited from 11 European countries, showed that Permixon 320 mg/day produced similar results to tamsulosin 0.4 mg/day (Omnic) (Debruyne et al 2002). More specifically, both treatments reduced the IPSS by an average of 4.4 in 80% of subjects. Those patients with the most severe disease experienced the greatest improvement in IPSS total score, with mean changes greater in the Permixon group than in the tamsulosin group (–8.0 and –6.8, respectively). With regard to safety, both treatments were considered well tolerated; however, ejaculation disorders were significantly more frequent with tamsulosin (4.2%) than with Permixon (0.6%). Although these results are promising, this study has been criticised for not including a placebo group as a comparator.

In a short 3-week study, Grasso et al (1995) compared the effects of alfuzosin (7.5 mg/day) with saw palmetto (320 mg/day) in 63 BPH subjects under double-blind test conditions. Both treatments were found to be equally effective with regard to improving irritative score; with maximum and mean urine flow; however, alfuzosin was shown to more rapidly reduce symptoms of obstruction. Considering most studies have shown that 4–8 weeks' treatment with the herb is required to produce maximal effects, the effect seen at 3 weeks is encouraging.

An earlier study compared the effects of prazosin with saw palmetto in 45 patients with BPH over a 12-week period (Adriazola et al 1992). This study found that although both treatments reduced symptoms, prazosin was slightly more effective.

Changes to prostate size

It is still open to speculation as to whether saw palmetto affects prostate size, because studies have produced contradictory results (Aliaev et al 2002, Bent et al 2006, Pytel et al 2002). One open study of 155 men tested the effectiveness and tolerability of Permixon (160 mg twice daily) over 2 years (Pytel et al 2002), and not only detected a significant improvement in the IPSS and quality of life (QOL) marker, but also a decrease in prostate size and significant improvement in sexual function after the first year of treatment.

A longer 5-year study using Permixon in 26 subjects with BPH showed that a total daily dose of 320 mg twice daily also significantly reduced disease symptoms and improved QOL, while reducing prostate size by an average of 30% (Aliaev et al 2002).

> ***Clinical note — BPH***
> BPH occurs in more than 50% of men over the age of 50 years. It is a slow, progressive enlargement of the fibromuscular and epithelial structures of the prostate gland, which can lead to obstruction of the ureter and urine retention. Symptoms such as frequent and/or painful urination, painful perineal stress and a decrease in urine volume and flow can develop. The condition has four stages, with stage 1 considered mild, stages 2 and 3 considered more severe and often requiring pharmacological treatment, and stage 4 as severe and necessitating surgery.

In 2003, results from two animal studies showed that saw palmetto (whole berry and extract) significantly diminished prostatic hyperplasia (Talpur et al 2003). In contrast, the 2006 study discussed earlier failed to find a significant effect on prostate size (Bent et al 2006).

Commission E approves the use of saw palmetto for stages 1 and 2 of BPH (Blumenthal et al 2000).

Androgenetic alopecia

The idea of using saw palmetto for androgenetic alopecia (AGA) arose from the observation that finasteride appears to have some effect on this condition. One double-blind study has investigated the effects of saw palmetto as a potential therapeutic option, finding a highly positive response in 60% of subjects (Prager et al 2002). A second double-blind study of 48 men and women with AGA noted that mean hair density increased by 17% after 10 weeks of treatment with a topical lotion containing saw palmetto and by 27% after 50 weeks of treatment compared to baseline (Morganti et al as reported in Linde et al 2006, Ulbricht & Basch 2006).

Chronic prostatitis and pelvic pain

Evidence to support the herb's use in prostatitis is scarce. However, in April 2003, positive findings from a preliminary study using Permixon to treat symptoms of chronic prostatitis and chronic pelvic pain syndrome (CP/CPPS) were presented at the annual meeting of the American Urological Association (AUA 2003). The RCT involving 61 patients with category IIIB CP/CPPS found that 75% receiving active treatment experienced at least mild improvement in symptoms, compared with 20% of the control group. Furthermore, 55% of patients receiving Permixon reported moderate or marked improvement, compared with 16% of the control group. In contrast, results from a 2004 prospective, randomised, open-label study failed to find benefits for saw palmetto (325 mg daily) in men diagnosed with category III CP/CPPS (Kaplan et al 2004). After 1 year, the mean total National Institutes of Health Chronic Prostatitis Symptom Index score decreased from 24.7 to 24.6 ($P = 0.41$) and no benefits were seen for QOL or pain with saw palmetto treatment.

OTHER USES

Traditionally, saw palmetto has been used to treat a variety of urogenital conditions, such as impotence, male infertility and also as an aphrodisiac. It has also been used in female hirsutism, although its effectiveness in this condition is unknown.

DOSAGE RANGE

- Liposterolic extract: 320 mg/day in divided doses.
- Dried berry: 2–4 g.
- Liquid extract (1:2): 2–4.5 mL/day.

According to clinical studies

- 160 mg twice daily of liposterolic extract taken long term.

ADVERSE REACTIONS

The herb is generally well tolerated, with only non-specific symptoms reported, such as gastrointestinal upset, constipation, nausea, abdominal pain and diarrhoea. These minor complaints are generally resolved by taking the herb in association with meals (Maccagnano et al 2006).

The 1-year STEP study provided a detailed assessment of the potential toxicity of saw palmetto, including both symptomatic adverse effects, as well as asymptomatic laboratory abnormalities (Avins & Bent 2006). It found no evidence that consumption of saw palmetto extract (160 mg twice daily) over a period of 1 year was associated with any clinically important adverse effects. Relatively few participants suffered serious adverse events, and these were more common in the placebo-allocated participants. Additionally, no statistically significant differences were observed between the saw palmetto and placebo groups in the measured domains of sexual functioning with the exception of the perception-of-sexual-problems domain which showed a small but significantly greater improvement in the placebo group.

SIGNIFICANT INTERACTIONS

No controlled studies are available and theoretical interactions are difficult to predict, due to the poorly understood nature of the herb's mechanism of action.

Finasteride (and other 5-alpha reductase inhibitor agents)

Additive effect theoretically possible — potential beneficial effect, although the clinical significance is unknown.

Androgenic drugs

Theoretically, saw palmetto may reduce effectiveness of therapeutic androgens such as testosterone — observe patient for lack of drug effect.

CONTRAINDICATIONS AND PRECAUTIONS

If symptoms of BPH worsen, blood is detected in the urine, or acute urinary retention occurs, professional reassessment is required.

PREGNANCY USE

Use of saw palmetto during pregnancy is contraindicated due to the herb's hormonal effects. In clinical practice, it is not used in pregnancy.

PRACTICE POINTS/PATIENT COUNSELLING

- Substantial scientific evidence has shown that saw palmetto is an effective treatment for stages 1 and 2 of BPH in cases where the diagnosis of cancer is negative. It is as effective as finasteride and alpha-adrenoreceptor antagonist drugs such as tamsulosin and alfuzosin, although prazosin may be slightly more effective.
- Typically, symptom reduction is experienced within 1–2 months' treatment, which is well tolerated, and associated with fewer side effects than finasteride and tamsulosin.
- The herb does not affect PSA levels; therefore, PSA test results will be unaffected.
- If symptoms worsen, blood is detected in the urine or acute urinary retention occurs, seek professional advice.

PATIENTS' FAQs

What will this herb do for me?

Saw palmetto has been investigated in numerous scientific studies and shown to reduce symptoms of enlarged prostate with few side effects. There is also some early research suggesting that it may be useful in some forms of hair loss and prostatitis.

When will it start to work?

Symptom relief for enlarged prostate is generally experienced within 4–8 weeks.

Are there any safety issues?

Saw palmetto is well tolerated; however, occasionally mild gastrointestinal disturbances, headaches and rhinitis have been reported.

Schisandra

HISTORICAL NOTE Schisandra has an extensive history of use in Traditional Chinese Medicine (TCM). It has sour and warm qualities and is used to treat spleen and kidney 'deficiency', to restore Qi and also as a treatment for chronic cough, wheezing, diabetes, insomnia and palpitations.

OTHER NAMES
Chinese magnolia vine, gomishi, sheng-mai-san, wuweizi

BOTANICAL NAME/FAMILY
Schisandra chinensis (family Schisandraceae)

PLANT PART USED
Fruit

CHEMICAL COMPONENTS
Dibenzocyclooctene lignans (schisandrin, schisandrins A–C, schizabdrols, schisantherins and gomisin A), essential oil, malic, tartaric, nigranoic and citric acids, resins, pectin, vitamins A, C and E, niacin, beta-carotene, sterols, tannins and several minerals.

MAIN ACTIONS
Studies have been conducted with schisandra and a number of its constituents in isolation, such as schisandrin B and gomisin A. Currently, most evidence is derived from in vitro and animal studies, as it has not been significantly investigated in clinical studies.

Antioxidant
In vitro tests have identified antioxidant activity (Ohsugi et al 1999). More specifically, seven lignans isolated from schisandra have demonstrated stronger antioxidant activity than vitamin E at the same concentrations, with schisanhenol exhibiting the strongest effects (Lu & Liu 1992). An extract of schisandra and the isolated constituent schisandrin B have both demonstrated the ability

to significantly decrease alanine aminotransferase (ALT) and increase glutathione levels in CCL4-damaged liver in vivo (Chiu et al 2002). It appears that several constituents also have indirect antioxidant activity and can increase hepatic and myocardial glutathione levels (Yim & Ko 1999).

Hepatoprotective activity

Decreases hepatotoxic damage

Several in vitro and in vivo studies have identified hepatoprotective effects with schisandra against carbon tetrachloride toxicity (Ip et al 1995, Mak & Ko 1997, Zhu et al 1999, 2000, Chiu et al 2007). Research with schisandrin B suggests that it is the main constituent responsible for these beneficial effects (Ip et al 1995, Mak et al 1996, Pan et al 2002, Chiu et al 2007). Further investigation reveals that schisandrin B increases the efficiency of the hepatic glutathione antioxidant system, thereby inhibiting carbon tetrachloride-induced lipid peroxidation; however, additional mechanisms appear likely (Ip et al 1995). More recently, the whole extract of schisandra fruit was shown to induce glutathione S-transferases in vitro (Choi et al 2008).

Protection against paracetamol-induced liver damage has been demonstrated in two animal models using gomisin A (Yamada et al 1993, Kim et al 2008). In one study, gomisin A inhibited not only the elevation of serum aminotransferase activity and hepatic lipoperoxide content, but also the appearance of histological changes such as degeneration and necrosis of hepatocytes (Yamada et al 1993).

In 2003, protection against paracetamol-induced liver damage and D-galactosamine-induced liver damage was confirmed for a fractionated extract of *S. chinensis* in an experimental model (Nakagiri et al 2003).

Liver regeneration

Two animal studies have demonstrated that oral administration of gomisin A, a lignan isolated from *S. chinensis*, accelerates liver regeneration after partial hepatectomy and hastens recovery of liver function (Kubo et al 1992, Takeda et al 1987). The mechanism for these effects is not fully elucidated; however, gomisin A increases ornithine decarboxylase activity, which is important during the early stages of regeneration and suppresses fibrosis proliferation.

Anti-inflammatory

Schisandrin inhibits NO production, prostaglandin E(2) release, cyclo-oxygenase (COX)-2, nitric oxide synthase (iNOS) and nuclear factor-kappaB in vitro (Guo et al 2008). Animal studies have also identified anti-inflammatory activity for gomisin A, gomisin J and wuweizi C (Yasukawa et al 1992). Several lignans from schisandra, including gomisin N and schisandrol A, have shown potent inhibition of nuclear factor of activated T cells (NFAT) in vitro (Lee et al 2003). Excessive activation of NFAT has a significant role to play in autoimmune disease, but further study is needed to assess schisandra's usefulness in immunopathological disease states.

A water extract of schisandra has demonstrated potent effects in a mast cell line (Kang et al 2006). The extract inhibits TNF-alpha, IL-6 and granulocyte-macrophage colony-stimulating factor (GM-CSF) production. These effects may be due to schisandra inhibiting the degradation of IkappaB and therefore the translocation and activation of NF-kappaB. This may indicate a potential role for schisandra in the treatment of allergy. Similarly, another study found that schisandrin decreased scratching behaviour by inhibiting the IgE-antigen complex in vivo (Lee et al 2007).

OTHER ACTIONS

Inhibits leukotriene formation

Gomisin A has been found to inhibit the biosynthesis of leukotrienes by preventing the release of arachidonic acid in vitro (Ohkura et al 1990).

Platelet-activating factor antagonist

Several lignans inhibit platelet-activating factor in vitro (Lee et al 1999).

Cardioprotective effects

Schisandrin B demonstrated protective effects against ischaemia–reperfusion-induced myocardial damage in a dose-dependent manner in an animal model (Yim & Ko 1999). The myocardial protection was associated with an enhancement in myocardial glutathione antioxidant status. Both the whole extract and gomisin A have demonstrated vasorelaxant properties in isolated rat thoracic aorta, suggesting cardioprotective effects (Park et al 2007, Rhyu et al 2006).

Schisandra may also help to reduce cholesterol. Schisandrin B (50–200 mg/kg) was co-administered with either a high lipid diet or a cholesterol/bile salts mixture in vivo (Pan et al 2008). Hepatic total cholesterol and triglyceride levels were reduced by up to 50% and 52%, respectively as compared to control animals.

Antitumour

Extracts of schisandra have demonstrated anticancer activity against various cancer lines, including leukaemia and lung in vitro (Lin et al 2008, Min et al 2008). An in vivo study investigated the effects of schisandra in 70 rats with induced hepatocellular carcinoma over 28 days. The extract was found to effectively suppress the proliferation of the cancer cells (Loo et al 2007).

Neuroprotective

Preliminary in vitro data suggest that certain lignans from schisandra are protective against L-glutamate-induced neurotoxicity in rat cortical cells (Kim et al 2004). Schisandrin B (1–30 mg/kg for 15 days) has been shown to improve the outcome in a cerebral ischaemia/reperfusion model

in vivo (Chen et al 2008). The extract protected against damage by enhancing the cerebral antioxidant status.

Schisandrin B appears to improve cognition and hepatic functions in mice treated with tacrine, the common Alzheimer's dementia medication (Pan et al 2002). Schisandrin demonstrated the ability to reverse hyoscine-induced memory impairment in vivo by enhancing cholinergic function (Egashira et al 2008).

Bone mineralisation

Lignans isolated from the fruit and seeds of schisandra may be able to protect against bone loss. An in vitro study using UMR 106 cells demonstrated that the lignans (extracted in 95% ethanol) stimulated the proliferation and activity of alkaline phosphatase in osteoblasts (Caichompoo et al 2009).

Cytochromes and P-glycoprotein

Conflicting in vivo data suggest that certain constituents from schisandra, in particular gomisin C, may inhibit CYP450 3A4 activity (Iwata et al 2004). Various lignans from schisandra, including schisandrol A, gomisin A, schisandrin A and schisandrin B have demonstrated an inhibitory effect on P-glycoprotein in vitro (Fong et al 2007, Wan et al 2006, Yoo et al 2007, Pan et al 2006, Qiangrong et al 2005). The clinical importance of this is as yet unknown.

CLINICAL USE

The therapeutic activity of schisandra has not been significantly investigated under clinical trial conditions, so evidence is derived from traditional, in vitro and animal studies.

Liver damage, hepatoprotection

Traditionally, schisandra has been used to treat a variety of liver disorders. Hepatoprotective effects have been observed in test tube and animal studies; however, the clinical significance of these findings in humans remains unknown. Several encouraging clinical reports using an analogue of schisandrin C are available; however, it is not known whether these effects will be seen with *S. chinensis* (Akbar et al 1998). A pilot clinical study in 10 healthy subjects has evaluated the effects of schisandra and sesamin (a constituent of sesame oil) on blood fluidity due to the link between blood viscosity and liver dysfunction (Tsi & Tan 2008). The mixture was given for 1 week and blood fluidity was tested over 2 weeks, including 1-week post intervention. Blood passage time was reduced by 9.0% and 9.7% at 1 and 2 weeks, respectively, showing that the effect could be sustained for at least 1 week after cessation of treatment. The exact effects of schisandra in this formula are unknown.

Adaptogen

In TCM, schisandra is viewed as an adaptogen and prescribed with other herbs to increase resistance to physical and emotional stressors and to improve allostasis (see monographs on Korean ginseng and Siberian ginseng for further information about adaptogenic activity and allostasis).

OTHER USES

Traditionally, schisandra has been used to treat chronic cough and dyspnoea, diarrhoea, night sweats, irritability, palpitations and insomnia. Based on the herb's inhibitory effects on leukotriene biosynthesis and platelet-activating factor activity and anti-inflammatory effects, it is also used for asthmatic symptoms.

Infection

Schisandra is also used in combination with other herbal medicines to treat infection. One double-blind, randomised, placebo-controlled pilot study found that a commercial product known as ImmunoGuard significantly reduced the duration, frequency and severity of attacks in patients with familial Mediterranean fever (Amaryan et al 2003). The dose regimen used was four tablets taken three times daily for 1 month. The ImmunoGuard product contains a fixed combination of *Andrographis paniculata* Nees., *Eleutherococcus senticosus* Maxim., *Schisandra chinensis* Bail. and *Glycyrrhiza glabra* L. special extracts, which are standardised for the content of andrographolide (4 mg/tablet), eleuteroside E, schisandrins and glycyrrhizin, respectively. Although these results are encouraging, it is not known to what extent schisandra contributed to the outcome.

A double-blind, placebo-controlled, randomised pilot study investigated the effects of another preparation known as Chisan (containing schisandra (51.0%), Rhodiola (27.6%) and Siberian ginseng (24.4%)) on recovery time and quality-of-life scores in patients with acute non-specific pneumonia (Narimanian et al 2005). Sixty participants were randomised to receive the standard treatment of cephazoline, bromhexine and theophylline or the standard treatment plus the herbal mixture (20 mL twice a day standardised to contain shisandrin 0.177 mg/mL and gamma-shisandrin 0.105 mg/mL) for 10–15 days. Participants in the active group reported significant improvements in recovery time and quality-of-life scores. The requirement for antibiotics was on average 2 days shorter for those participants taking Chisan. All of these herbs have been celebrated for their adaptogenic effects and this may, at least in part, be responsible for the results. The individual effects of schisandra in this formula, however, are unknown.

DOSAGE RANGE

As clinical research is lacking, the following dosages come from Australian manufacturers' recommendations.

- Dried fruit: 1.5–6 g/day.
- Liquid extract (1:2): 3.5–8.5 mL/day or 25–60 mL/week.

TOXICITY

Insufficient reliable information is available.

ADVERSE REACTIONS

Mild gastrointestinal discomfort.

SIGNIFICANT INTERACTIONS

Controlled studies are not available, so interactions are speculative.

Drugs metabolised by CYP 3A4

In vivo evidence suggests an inhibitory effect on CYP 3A4 activity, particularly for the gomisin C constituent; however, clinical studies have not yet confirmed the effect (Iwata et al 2004). Based on this observation, serum levels of drugs chiefly metabolised by CYP 3A4 may increase — observe patient.

P-glycoprotein (P-gp) substrates

Various lignans from schisandra, including schisandrol A, gomisin A, schisandrin A and B and schisandrin B have demonstrated an inhibitory effect on P-glycoprotein in vitro (Fong et al 2007, Wan et al 2006, Yoo et al 2007, Pan et al 2006, Qiangrong et al 2005); however, the effect has not been confirmed clinically. Theoretically, the bioavailability of P-gp substrates could be increased — observe patient.

CONTRAINDICATIONS AND PRECAUTIONS

Insufficient reliable information is available.

PREGNANCY USE

Insufficient information is available to establish safety.

PRACTICE POINTS/PATIENT COUNSELLING

- *S. chinensis* is popular in TCM and is used to increase resistance to physical and emotional stressors and regarded as an adaptogen.
- Traditionally, schisandra has been used to treat chronic cough and dyspnoea, diarrhoea, night sweats, irritability, palpitations and insomnia.
- It is commonly used as a liver tonic, and preliminary evidence has identified significant hepatoprotective effects.
- Schisandra exerts direct antioxidant activity and increases hepatic and myocardial glutathione levels, thereby increasing antioxidant systems within the heart and liver.
- Overall, little clinical evidence is available; therefore, much information is still speculative and based on in vitro and animal research and traditional use.

PATIENTS' FAQs

What will this herb do for me?

Schisandra is often prescribed to increase physical and emotional resilience and as a liver tonic. It has antioxidant activity, and early research suggests that it may have significant protective benefits for the liver.

When will it start to work?

This is uncertain due to insufficient research being available.

Are there any safety issues?

This is uncertain due to insufficient research being available.

Selenium

HISTORICAL NOTE During his travels in the 13th century, Marco Polo first reported what is thought to be selenium toxicity in grazing animals. He observed that certain grazing areas in China were associated with horses developing diseased hooves (Hendler & Rorvik 2001). It is now known that parts of China have the highest selenium soil concentrations in the world and diseased hooves were likely to be due to selenium toxicity. It was not until nearly 500 years later, in 1817, that selenium was actually discovered (Tinggi 2003) and the fact that it is essential in mammals was not discovered until 1957 (Navarro-Alarcon & Lopez-Martinez 2000). In 1979, the importance of selenium in human nutrition was further reinforced when Chinese researchers reported that selenium supplementation prevented the development of Keshan disease, a cardiomyopathy seen in children living in selenium-replete areas, and New Zealand workers reported a clinical response to selenium supplementation in a selenium-depleted patient (Shils et al 2006).

BACKGROUND AND RELEVANT PHARMACOKINETICS

Selenium is an essential trace element that enters the food chain through incorporation into plants from the soil. Selenium is mainly present in the form of selenite in acid soils, which is poorly assimilated by crops, whereas for alkaline soils, it is in the form of selenate, which is more soluble and assimilated by crops. When taken in supplement form, animal and human trials demonstrate that bioavailability of organic forms of selenium (Se-methionine and Se-cysteine) is higher than that obtained for inorganic forms (selenite and selenate) (Navarro-Alarcon & Lopez-Martinez 2000).

The variation in selenium content of adult humans living in different parts of the world is testimony to the influence of the natural environment on the selenium content of soils, crops and human tissues. According to a WHO report, adults in New Zealand have approximately 3 mg selenium in their bodies compared with 14 mg in some Americans.

Selenium is readily absorbed, especially in the duodenum and also in the caecum and colon. Vitamins A, E and C can modulate selenium absorption, and there is a complex relationship between selenium and vitamin E that has not been entirely elucidated for humans (Bates 2005). Selenium enters the body in two major forms: Se-methionine, which

is derived from plants, and Se-cysteine, which is mainly derived from animal selenoproteins (Shils et al 2006). Metabolism is complex and occurs via several routes for the different selenoproteins. Se-methionine enters the methionine pool where it undergoes the same fate as methionine until catabolised. Once the selenium from Se-methionine is liberated by the trans-sulfuration pathway in the liver or kidney, it is able to be used by peripheral cells. Ingested selenite, selenate and selenocysteine are metabolised to selenide. Urinary excretion accounts for 50–60% of total excretion of selenium and homeostasis is achieved through regulation in the kidney. Volatile forms of selenium are exhaled when intake is very high and presents a significant route of excretion at this level.

CHEMICAL COMPONENTS

In human tissues, it is found as either L-selenomethionine or L-selenocysteine.

FOOD SOURCES

The most concentrated food sources are brewer's yeast, wheatgerm, meats, fish and seafood, Brazil nuts, garlic and organ meats.

DEFICIENCY SIGNS AND SYMPTOMS

Selenium deprivation reduces the activity of selenium-dependent enzymes and has widespread effects. Characteristic signs of selenium deficiency have not been described in humans, but very low selenium status is a factor in the aetiologies of a juvenile cardiomyopathy (Keshan disease) and a chondrodystrophy (Kashin-Beck disease) that occur in selenium-deficient regions of China.

Low selenium status has been associated with:

- loss of immunocompetence (Ongele et al 2002)
- increased risk of developing certain cancers (Clark et al 1998)
- reduced male fertility (Scott et al 1998, Xu et al 2003)
- poorer prognosis in HIV infection and AIDS (Baum et al 1997, Campa et al 1999)
- greater incidence of depression, anxiety, confusion and hostility (Rayman 2000)
- compromised thyroid hormone metabolism (particularly when iodine deficiency is also present) (Gartner et al 2002)
- asthma and atopy (Kadrabova et al 1996, Misso et al 1996, Omland et al 2002)
- rheumatoid arthritis (Zamamiri-Davis et al 2002)
- possibly, increased inflammatory processes (Zamamiri-Davis et al 2002)
- changes to drug-metabolising enzymes, including the cytochrome P450 system, with some activities increasing and others decreasing (Shils et al 2006).

Low selenium status may contribute to the aetiology of several diseases, while in others this state exacerbates disease progression, such as in HIV infection.

People at risk of marginal selenium deficiency include those living in areas of low environmental selenium, such as some regions of New Zealand, people receiving long-term total parenteral nutrition (TPN), alcoholics, and those with liver cirrhosis, malabsorption syndromes, cystic fibrosis, coeliac disease and AIDS.

MAIN ACTIONS

Antioxidant

Selenium is an integral part of thioredoxin reductase and the glutathione peroxidases and therefore is intimately involved in the body's antioxidant systems. These enzymes are involved in controlling tissue levels of free radical molecules and maintain cell-mediated immunity.

Chemopreventative

Chemoprotective effects of selenium have been indicated by an epidemiological relationship, by RCTs and by experimental studies of selenium and known carcinogens in the development of specific cell lines. Overall, it appears that selenium works by inhibiting important early steps in carcinogenesis.

Several mechanisms have been postulated to explain the chemopreventative effect of selenium, including protection against oxidative damage, alterations to immune and metabolic systems, alterations to carcinogen metabolism, production of cytotoxic selenium metabolites, inhibition of protein synthesis, stabilisation of genetic material facilitating DNA repair by activation of p53, inhibition of Nuclear factor-kappa B (NF-kappa B) and stimulation of apoptosis (Christensen et al 2007, Chun et al 2006, Clark et al 1996, El Bayoumy 2001, Schrauzer 2000, Seo et al 2002). One study demonstrated that combining vitamin E succinate and methylselenic acid produces a synergistic effect on cell growth suppression, primarily mediated by augmenting apoptosis (Zu & Ip 2003).

In humans, the chemopreventative effect is strongest for individuals with the lowest selenium status; however, it is still unclear whether low selenium status is implicated in the aetiology of cancer or whether it produces a state of increased susceptibility to the effects of carcinogens.

Immunomodulation

Confirmed in both animal studies and human trials, immunomodulation is in part due to improved activation and proliferation of B-lymphocytes and enhanced T-cell function (Gazdik et al 2002a, 2002b, Hawkes et al 2001, Kiremidjian-Schumacher & Roy 1998, Ongele et al 2002). Interestingly, selenium concentrations significantly decrease during stages of acute infection, suggesting increased use and/or excretion or decreased absorption during this period (Sammalkorpi et al 1988).

Thyroid hormone modulation

Selenium is required for normal thyroid hormone synthesis, activation and metabolism (Sher 2001). Three different selenium-dependent iodothyronine deiodinases (types I, II, and III) can both activate

and inactivate thyroid hormone, making selenium an essential element for normal development, growth and metabolism through the regulation of thyroid hormones.

OTHER ACTIONS

Male fertility

Selenium is required for testosterone synthesis, normal sperm maturation and sperm motility (Rayman & Rayman 2002). Two clinical studies have confirmed this association (Scott et al 1998, Vezina et al 1996) and identified selenium supplements as able to increase sperm motility. The effect of selenium in spermatogenesis may be due to several mechanisms, including the activity of the selenium-dependent enzyme phospholipid hydroperoxide glutathione peroxidase (GPx4) (Flohe 2007), altering oxidative stress-mediated apoptosis in germ cells (Kaushal & Bansal 2007a, 2007b), and the modulation of transcription factor NF-kappaB (Shalini & Bansal 2006, 2007a). Interestingly, animal studies suggest that detrimental effects on fertility are associated with either too little or excessive selenium intake (Shalini & Bansal 2007b, 2008).

Anti-inflammatory

Selenium deficiency produces a significantly increased COX-2 protein expression, as well as higher PGE_2 levels, according to one in vitro study (Zamamiri-Davis et al 2002). It has also been theorised that selenium may decrease leukotriene production (McCarty 1984). In vivo tests have identified anti-inflammatory activity in the lung with selenium, which is thought to relate to an increase in glutathione levels and immune parameters (Jeong et al 2002).

Reduces heavy metal toxicity

Selenium protects against toxicity of some heavy metals, such as cadmium, arsenic, lead, silver and mercury (Berry & Galle 1994, Bolkent et al 2008, Chuang et al 2007, El-Sharaky et al 2007, El-Shenawy & Hassan 2008, Lindh et al 1996, Navarro-Alarcon & Lopez-Martinez 2000, Yiin et al 1999a, 1999b, 2000, 2001). A physiological role for selenium in counteracting heavy metal poisoning has been proposed (Shils et al 2006). It appears that the form of selenium is important, as inorganic selenium has been shown to enhance the toxic effects of inorganic arsenic by increasing its retention in tissues and suppressing its metabolism in vitro (Styblo & Thomas 2001).

Antiatherogenic activity

Selenium supplementation reduces high-fat diet-induced atherosclerosis, according to an in vivo study (Kang et al 2001). In healthy subjects fed a test meal high in lipid hydroperoxides, selenium supplementation counteracted the postprandial synthesis of the atherogenic form of LDL (Natella et al 2007). According to studies with experimental models, beneficial effects on lipid metabolism are due to significant up-regulation of LDL receptor activity and mRNA expression (Dhingra & Bansal 2006a), and down-regulation of hypercholesterolaemia-induced changes in apolipoprotein B (apoB) and 3-hydroxy 3-methylglutaryl coenzyme A (HMG-CoA) reductase expression during experimental hypercholesterolaemia (Dhingra & Bansal 2006b).

CLINICAL USE

Deficiency states: prevention and treatment

Traditionally, selenium supplementation has been used to treat deficiency or prevent deficiency in conditions such as malabsorption syndromes. In addition, the elderly are at increased risk of selenium deficiency. Poor levels are negatively associated with subjective indicators of quality of life (QOL) in older people, such as self-perceived health, chewing ability, physical activity (Gonzalez et al 2007), muscle strength (Beck et al 2007, Lauretani et al 2007) and cognitive function (Akbaraly et al 2007, Gao et al 2007). Supplementation in this population where deficiency has been demonstrated is warranted.

Cancer: prevention and possible adjunct to treatment

Selenium supplementation is used to reduce total cancer incidence and mortality.

Chemoprevention

Collectively, geographical studies, epidemiological data, laboratory bioassays, studies in over 12 different animal models and human intervention trials generally support a protective role for selenium against the development of cancer; however, results are not always consistent. Further research is required to better determine characteristics of responders, optimal dosage and dose forms. Populations who live in low-selenium environments and have low selenium intakes tend to have higher cancer mortality rates. However, the results from epidemiological studies have been less consistent and show that the effect may be strongest in males.

Total cancer incidence and mortality

The Nutritional Prevention of Cancer (NPC) Trial was a large multicentre, double-blind, randomised, placebo-controlled trial conducted with 1312 patients with a history of basal cell or squamous cell carcinomas of the skin, which investigated the effects of 200 microgram selenium daily (as 500 mg brewer's yeast) as a cancer protective agent (Clark et al 1998). Selenium supplementation in this population did not alter future incidence of skin cancer; however, it significantly reduced total cancer mortality, total cancer incidence by 37% and the incidences of lung, colorectal and prostate cancers by 46%, 58% and 63%, respectively. Results from further continuation of the trial have continued to find a protective effect for selenium in total cancer incidence and the individual cancers; however, this now appears to be restricted to people with low baseline plasma levels and most pronounced for colorectal cancer and current smokers, whereas protective effects in prostate cancer was further restricted to lower baseline levels of prostate-specific antigen (PSA: ≤4 ng/mL)

(Duffield-Lillico et al 2002, 2003, Reid et al 2002, 2006). However, in a recent small randomised, double-blinded adjunct study to the NPC Trial, subjects receiving 400 microgram/day (as selenised yeast) did not have a lower total cancer incidence compared to those receiving the matched yeast placebo. Whilst selenium at 200 microgram/day lowered cancer incidence by 25%, this protective effect was not seen when a double dose was used (Reid et al 2008).

The association between selenium levels and all-cause and cause-specific mortality was recently examined in a large prospective study involving 13,887 adult participants involved in the Third National Health and Nutrition Examination Survey (NHANES III). At the 12-year follow-up, both all-cause and cancer mortality were found to be reduced with increasing serum selenium levels up to <130 ng/mL, but a gradual increase in mortality was seen at higher levels exceeding 150 ng/mL (Bleys et al 2008).

Liver cancer

A trial involving 130,471 individuals living in a high-risk area for viral hepatitis and liver cancer (Quidong, China) found that table salt enriched with sodium selenite reduced the incidence of liver cancer by 35% during the 8-year follow-up period, whereas no changes were observed for the control groups (Yu et al 1997). Additionally, incidences of liver cancer began to rise after withdrawal of selenium supplementation. Patients with hepatocellular carcinoma had significantly lower serum selenium levels (along with iron, copper, and zinc) compared to those in the control group. The researchers speculated that lower levels of these minerals may act as biomarkers of the increased severity of viral hepatic damage (Lin et al 2006).

Prostate cancer

Epidemiological and clinical data suggest that selenium may prevent prostate cancer. A large case-control study involved 33,737 males and identified an association between higher selenium status and a reduced risk of prostate cancer (Yoshizawa et al 1998). The study showed that men consuming the most dietary selenium (assessed indirectly by measuring toenail selenium levels) developed 65% fewer cases of advanced prostate cancer than those with the lowest intake.

Strong evidence for a protective effect of selenium against prostate cancer comes from the Nutritional Prevention of Cancer (NPC) Trial, as described above, in which the incidence of prostate cancer was reduced in the selenium group by two-thirds as compared to placebo. Further follow-up has revealed that selenium supplementation continues to show a marked reduction on the incidence of prostate cancer with strongest effects seen in men with a PSA <4 ng/mL and those with the lowest serum selenium levels at study entry (Duffield-Lillico et al 2003). It is interesting to note that the NPC Trial was conducted in an area with low soil selenium content, and this may in part explain the conflicting results in studies conducted in various countries around the world.

A meta-analysis of 20 epidemiological studies found an inverse association between selenium levels (assessed in studies by serum, plasma and toenail) and risk of prostate cancer (Brinkman et al 2006). This supports the findings of an earlier meta-analysis of 16 studies (Etminan et al 2005). Similarly, in a recent prospective, case-control study (n = 130), men with newly diagnosed prostate cancer had significantly lower serum selenium compared to healthy controls (66.3 microgram/L versus 77.5 microgram/L, respectively). An increase of 10 microgram/L in serum selenium concentration was associated with a significant decrease in risk of prostate cancer (Pourmand et al 2008).

In contrast, no association between selenium and cancer has been found in some studies. Peters et al (2007) observed that there was no inverse association between prediagnostic serum selenium concentration and the risk of prostate cancer in a large cohort study with 724 cases and 879 matched controls in a nested case-control study. However, higher serum selenium levels may reduce prostate cancer risk in men who reported a high intake of vitamin E, in multivitamin users and in smokers (Peters et al 2007). Another prospective cohort study, the Vitamins And Lifestyle (VITAL) study, investigated the association of vitamin E and selenium supplementation with prostate cancer. No association was found between long-term selenium supplementation (average of 10 years) and prostate cancer risk with an average intake of >50 microgram/day compared to non-users. Supplementation for longer than an average of 10 years, however, was associated with a statistically non-significant reduction in prostate cancer among older men (≥70 years) (Peters et al 2008). Hopefully, the controversy may become clearer with the results from the currently underway Selenium and Vitamin E Cancer Prevention Trial (SELECT), which is a randomised, prospective, double-blind study designed to determine whether 200 microgram L-selenomethionine, 400 mg of racemic alpha-tocopheryol and an optional multivitamin containing no selenium or vitamin E can reduce the risk of prostate cancer among healthy men. It is anticipated that over 32,000 men will be involved in the study and final results will be available in 2013 (Klein et al 2001).

High-grade prostatic intraepithelial neoplasia (HGPIN) is the key premalignant lesion for prostate cancer. In a randomised, placebo-controlled trial, the role of selenium 200 microgram/day (in the form of selenomethionine) in preventing prostate cancer in men with HGPIN is currently being undertaken. The results of this 3-year study are due in 2009 (Marshall et al 2006).

Stomach and oesophageal cancers

A large study of nearly 30,000 people demonstrated a protective effect for a combination of selenium, beta-carotene and vitamin E against the development of cancer of the gastric cardia and oesophagus (Mark et al 2000). Supplementation also reduced the cancer mortality rate compared with those not receiving supplementation. Protective effects on total cancer deaths developed slowly, appearing

after 1 year of treatment and the effect on stomach cancer appeared after 2 years. Gene–selenium interactions may influence an individual's susceptibility to oesophageal cancer. Individuals with polymorphisms in aldehyde dehydrogenase-2 Lys/Lys, X-ray repair cross-complementing 1 399Gln/Gln or Gln/Arg alleles, glutathione S-transferase isoenzyme Ile/Ile genotype or p53 (tumour suppressor gene) Pro/Pro genotype who consumed a low-selenium diet were at the greater risk of oesophageal squamous cell carcinoma, especially when combined with tobacco and alcohol intake (Cai et al 2006a, 2006b).

The protective role of selenium on gastric cancer risk may occur only in those with low baseline selenium. In a recent study where the levels of selenium were relatively high in both cases and controls, the lowest risk of gastric cancer was found in those with the lowest quartile of selenium level (assessed by toenail levels), whereas those with the highest risk were in the second highest quartile (Koriyama et al 2008).

Colorectal cancer

The incidence of colorectal adenomas, the precursor to most colorectal cancers, may be reduced by selenium. An inverse association between selenium and adenomas has been found in numerous studies, particularly among smokers and those with low baseline serum or plasma selenium (Clark et al 1993, Connelly-Frost et al 2006, Fernandez-Banares et al 2002, Jacobs et al 2004, Peters et al 2006, Reid et al 2006, Russo et al 1997). However, others have reported no association in risk (Early et al 2002, Wallace et al 2003). Compared to age-matched healthy controls, patients with colorectal cancer were found to have statistically lower serum selenium levels. Furthermore, a higher level of selenium was present in the cancerous tissue than in healthy tissue, though it is unclear whether this is the reason for the decreased selenium in the serum or whether the decreased serum levels occur prior to the development of colorectal cancer (Charalabopoulos et al 2006).

Premalignant skin lesions

Increased selenium status may reduce the incidence of arsenic-related premalignant skin lesions (Chen et al 2007, Huang et al 2008). This is consistent with several observational studies that found a protective association between plasma selenium level and the risk of non-melanoma skin cancer (Breslow et al 1995, Clark et al 1984, Karagas et al 1997). Long-term selenium supplementation may exert a protective effect against arsenic-induced premalignant skin lesions by reversing some of the changes in gene expression (Kibriya et al 2007).

Female reproductive

Selenium status measured by plasma levels and erythrocyte glutathione peroxidase activity was significantly lower in patients with cancer or benign neoplasia of the reproductive tract (uterus or ovary). Furthermore, examination of tissue margins of the tumours following surgery revealed significantly higher selenium concentrations compared to healthy tissue margins of healthy tissue. This suggests a protective role of selenium in the development of these reproductive tumours and a compensatory up-regulation of antioxidant defence systems in tumours due to persistent oxidative stress (Piekutowski et al 2007).

Oral Cancer

Selenium levels are significantly associated with risk of oral squamous cell carcinoma, with lower levels found in patients compared to both healthy controls and those with precancerous lesions (oral submucous fibrosis and oral leucoplakia) (Khanna & Karjodkar 2006).

Reducing mortality from HIV infection

Selenium appears to be important in HIV infection, with plasma selenium a strong predictor of disease outcome in both adults and children (Baum & Shor-Posner 1998, Baum et al 1997, Campa et al 1999).

Low selenium status is common in HIV-positive patients and is associated with a decline in Th (CD4) cell counts (Bates 2005). In a double-blind, randomised, placebo-controlled trial, selenium supplementation (200 microgram/day) for 9 months suppressed the progression of HIV-1 viral burden and indirectly improved CD4 counts in adult HIV-infected men and women (Hurwitz et al 2007). Low selenium is also associated with an increased incidence of mycobacterial diseases in HIV-1-seropositive drug users (Dworkin 1994, Dworkin et al 1986, 1989, Shor-Posner et al 2002). One small intervention trial using low-dose selenium supplements (80 microgram/day with 25 mg vitamin E) over 2 months has shown an improvement in general symptoms but no alterations to immunological or haemotological parameters (Cirelli et al 1991).

The protective role of selenium in HIV-infected pregnant women is less clear. One study found that low plasma selenium status was associated with increased risk of intrapartum transmission of HIV, risk of fetal and child mortality and the risk of small-for-gestational age (Kupka et al 2005). In contrast, in a recent randomised, double-blind, placebo-controlled trial, 200 microgram/day of selenium during and after pregnancy did not improve HIV disease progression, fetal mortality, prematurity or small-for-gestational age birth. Supplementation may however improve child survival after 6 weeks (Kupka et al 2008).

Selenium and selenium-dependent glutathione peroxidase (GSH-Px) are important for antioxidant protection and reducing oxidative damage in HIV. Antioxidant defences are increased in selenium-replete HIV patients due to the increase in oxidative stress induced by the infection (Stephensen et al 2007). However, in those with poor selenium levels and subsequently reduced GSH-Px defences, the increased oxidative stress may increase HIV progression (Ogunro et al 2006).

Cardiovascular disease prevention

Selenium may decrease cardiovascular disease mortality; however, epidemiological studies have produced mixed results. A meta-analysis examining the

relationship between selenium and coronary heart disease found an overall positive effect in observational studies (11 out of 14 cohort studies and 9 of 11 case-control studies). A 50% increase in selenium concentrations was associated with a 24% reduced risk of coronary events. However in the randomised controlled trials, supplementation with selenium (4 out of 6 trials using multiple nutrients) had only a non-significant 11% reduction in coronary events (Flores-Mateo et al 2006).

In contrast, no significant primary preventative effect was seen for selenium supplementation (200 microgram/day) and incidence of cardiovascular disease, myocardial infarction, stroke or all cardiovascular disease mortality in the NPC study (Stranges et al 2006). Lack of association was confirmed when analyses were further stratified by tertiles of baseline plasma selenium concentrations.

An individual's selenium status may play an important role in its effectiveness in attenuating cardiovascular disease, with both too little and too much increasing risk. In a recent study, Bleys et al (2008) found that while cardiovascular and coronary heart disease mortality decreased as serum selenium levels increased up to levels of 120 ng/mL, at levels above this the mortality risk was not statistically increased (Bleys et al 2008). Many of the studies investigating selenium and cardiovascular disease have been conducted in European countries that have a lower selenium intake compared to countries such as the United States. It is possible that selenium is most effective at preventing cardiovascular disease in areas with intake levels less than those in the United States (Bleys et al 2008).

The correlation between selenium status and cardiovascular disease may be stronger in the elderly who typically have lower selenium levels. In a 9-year longitudinal study, the decline in selenium associated with ageing was greater in those who were obese or had experienced cardiovascular events (Arnaud et al 2007), suggesting that a greater intake may be necessary in these individuals to counter oxidative stress.

With regard to secondary prevention, an intervention study conducted by Korpela et al (1989) in subjects having suffered from acute myocardial infarction has produced encouraging results. The randomised, double-blind trial compared the effects of selenium-rich yeast (100 microgram/day) with placebo, concurrently with standard treatment in 81 patients with acute myocardial infarction. During the 6-month follow-up period, there were no cardiac deaths in the selenium-treated group compared with four receiving placebo, and two non-fatal re-infarctions in the placebo group compared with only one receiving selenium supplementation.

Low selenium status may contribute to the development of hypertension. In a cross-sectional longitudinal study involving 710 Flemish subjects with an average baseline blood pressure of 130/77 mmHg, an inverse relationship was found between blood selenium and blood pressure in men at follow-up (median of 5.2 years). A 20-microgram/L higher baseline blood selenium concentration was associated with a 37% lower risk of developing high-normal BP or hypertension. No association was found in women (Nawrot et al 2007).

Compared to premenopausal women, postmenopausal women had lower erythrocyte selenium levels, which were associated with significantly higher levels of total cholesterol, triglycerides and LDL cholesterol. This association remained after controlling for age, smoking status and body mass index (Karita et al 2008).

Diabetes

The relationship between selenium and diabetes is complex. Selenium appears to be involved in several key aspects of pancreatic beta-cell and islet function, increasing insulin content and secretion (Campbell et al 2008). Compared to healthy controls, diabetic patients have been found to have lower selenium levels (assessed by toenail levels) (Rajpathak et al 2005). Supplementation with selenium in diabetic patients has been found to reduce activation of NF-kappa B and levels of oxidative stress, and thus may help to prevent vascular complications (Faure et al 2004). Selenium has also been found to inhibit high glucose- and high insulin-induced expression of adhesion molecule via modulation of p38 pathway, and may therefore help to prevent the development of atherosclerosis in diabetics (Zheng et al 2008). However, recent data suggest that chronically high-selenium levels in selenium-replete populations may increase the risk of developing diabetes. Results from the NHANES III found that those in the highest quintile of serum selenium had a statistically significant increased prevalence of diabetes compared with those in the first quintile (Bleys et al 2007). Similarly, secondary analysis of the NPC trial found that 200 microgram/day of selenium for an average of 7.7 years did not prevent diabetes and statistically significantly increased the risk of type 2 diabetes compared to the placebo group (Stranges et al 2007).

Selenium may play a protective role in gestational diabetes. A cross-sectional study involving 178 pregnant women (24–28 weeks of gestation) found a significant inverse correlation between selenium and blood glucose levels in patients with gestational diabetes mellitus or glucose intolerance having lower serum selenium levels compared to healthy controls (Kilinc et al 2008). This supports similar findings (Al-Saleh et al 2004, 2007, Bo et al 2005, Hawkes et al 2004, Molnar et al 2008, Tan et al 2001).

Asthma

Asthma, respiratory symptoms and ventilatory function have been associated with lowered circulatory selenium status and glutathione peroxidase activity (Devereux & Seaton 2005, Hasselmark et al 1990, Kadrabova et al 1996, Misso et al 1996, Omland et al 2002). When these observations are coupled with in vivo evidence of anti-inflammatory activity in the lung for selenium, it is not surprising that there is growing interest in using selenium supplementation to improve asthmatic symptoms and disease management. A small number of intervention studies have been conducted, producing mixed results (Gazdik et al 2002a, 2002b, Hasselmark et al 1993).

Hasselmark et al conducted a randomised, double-blind study involving 24 patients with intrinsic asthma. A dose of 100 microgram sodium selenite was administered for 14 weeks, resulting in significant increases in serum selenium and platelet glutathione peroxidase activity, while no changes were observed with placebo. Clinical results varied, with significantly more treated patients improving on several parameters of lung function, such as airway responsiveness, clinical examination, medication use and subjective patient impressions. However, there were no significant improvements over baseline in any individual clinical parameter. A small pilot study of 17 asthmatics dependent on corticosteroid medication found that a dose of 200 microgram selenium daily taken over a 96-week period reduced both inhaled and systemic corticosteroid requirements. The same study observed selenium supplementation enhancing immunity (Gazdik et al 2002a, 2002b).

Results from several recent studies have not demonstrated a beneficial effect of selenium in asthma. Meta-analysis of data from a recent case-control study involving 569 asthmatic patients and 576 healthy controls in 14 European centres found no overall effect between plasma selenium levels and the risk of asthma. There was heterogeneity in results among the centres, however with a 10 microgram/L increase in plasma selenium associated with a 52% decreased risk of asthma in Lodz, but a 35% increase in risk in Ghent and a 68% increase in risk in Amsterdam (Burney et al 2008). These results are similar to those from a randomised, double-blind, placebo-controlled trial involving 197 asthmatic subjects given either a selenium supplement (high-selenium yeast preparation of 100 microgram) daily or placebo for 6 months. Whilst the baseline plasma selenium levels increased by 48% in the treatment group, there was no significant difference between the groups with regard to either the primary outcome (asthma-related QOL score) or secondary outcomes, including lung function, asthma symptom scores, peak flow and bronchodilator usage (Shaheen et al 2007).

Selenium appears to have a protective role in reducing childhood wheezing. Low plasma selenium levels during early pregnancy and in the neonate have been found to increase the risk of early childhood wheezing, although this positive association was no longer found at the age of 5 (Devereux et al 2007). Similarly in a study of 61 children aged 0.3–5 years with no atopic history, lower serum selenium levels were found in those with frequent wheezing compared with those in healthy controls, and selenium levels were significantly correlated with the number of wheezing episodes experienced in the previous year. This protective effect may be due to preventing the progression of respiratory infections which subsequently contribute to the development of wheezing (Kocabas et al 2006).

Autoimmune thyroiditis

Selenium appears to play an important role in the health of thyroid gland function and the prevention of disease. In a study of differences in selenium levels between those with thyroid disease and those without, selenium levels were significantly decreased in those with both benign thyroid disease (subacute and silent thyroiditis) and malignant thyroid disease (follicular and papillary thyroid carcinoma) compared to healthy controls (Moncayo et al 2008). Similarly in a study of patients with Graves' disease, those with the highest serum selenium levels (>120 microgram/L) were more likely to be in disease remission (Wertenbruch et al 2007).

Selenium supplementation may improve inflammatory activity in chronic autoimmune thyroiditis patients, as evidenced by a significant reduction in the concentration of thyroid peroxidase antibodies (TPO-Ab) to 63.8% in selenium-supplemented subjects versus 88% ($P = 0.95$) in placebo subjects (Gartner et al 2002). The randomised study of 70 females (mean age 47.5 years) compared 200 microgram sodium selenium daily orally for 90 days to placebo. A follow-up crossover study of 47 patients from the initial 70 was conducted for a further 6 months (Gartner & Gasnier 2003). The group that continued to take sodium selenite (200 microgram/day) experienced further significant decreases, whereas the group that ceased selenium use experienced a significant increase. The patients who received 200 microgram sodium selenite after placebo also experienced a significant decrease in levels of TPO-Ab. More recently, in a prospective study of 80 patients with Hashimoto's thyroiditis receiving 200 microgram selenium (as selenomethionine) resulted in a significant 9.9% decrease in TPO-Ab levels after 6 months. In those patients who continued to take the selenium for another 6 months, TPO-Ab levels decreased by another 8% whilst those who ceased treatment experienced a 4.8% increase (Mazokopakis et al 2007). The role of selenium in the treatment of autoimmune thyroiditis (AIT) may be limited to those with a higher level of disease activity. In consecutive AIT patients randomised to receive 200 microgram/day of selenium for 3 months in addition to levothyroxine medication, there was no significant decrease in TPO-Ab levels or difference in cytokine patterns compared to either pre-treatment levels or those in the placebo group (Karanikas et al 2008). The authors suggest that the lack of effect in this study may be due to the lower initial TPO-Ab levels compared to those reporting positive results, such as the studies above.

In a study investigating the efficacy of 100 microgram and 200 microgram doses of selenomethionine in reducing serum concentrations of TPO-Ab in patients with AIT, Turker et al (2006) concluded that the larger dose was more effective (Turker et al 2006).

Selenium supplementation (200 microgram/day) during and after pregnancy inhibits the post-partum progression of autoimmune chronic thyroiditis in those with positive thyroid peroxidase antibodies. In a prospective, randomised, placebo-controlled study, patients supplemented with selenium had significantly reduced thyroid inflammatory activity and the incidence of hypothyroidism compared to those receiving no treatment (placebo) (Negro et al 2007).

Rheumatoid arthritis (RA)

Selenium supplements have been used in RA because of its antioxidant activity and the observation that some patients with RA have been reported with low selenium status (O'Dell et al 1991, Rosenstein & Caldwell 1999). One double-blind, placebo-controlled intervention study of 55 patients with moderate RA found that both placebo and selenium appeared to have significant effects on a number of symptoms; however, only selenium significantly improved arm movements and sense of wellbeing (Peretz et al 2001).

Lowered male fertility

Xu et al (2003) identified a significantly positive correlation between selenium levels and sperm density, sperm number, sperm motility and sperm viability in human volunteers. Similarly, Akinloye et al (2005) reported a significant inverse correlation between serum selenium level and sperm count and serum testosterone, and seminal plasma selenium with spermatozoa motility, viability and morphology (Akinloye et al 2005). Supplementation with selenium in selenium-replete subfertile men has been shown to improve sperm motility and the chance of successful conception in over half of treated patients (Scott et al 1998). When taken with vitamin E over 6 months, selenium produces a statistically significant increase in sperm motility, percent live and percent normal spermatozoa, with effects reversing after supplement cessation (Vezina et al 1996). Although results are encouraging, particularly for subfertile men with low selenium status, one negative intervention trial was located that found that supplementation had no effect (Iwanier & Zachara 1995).

General immune enhancement

Several intervention trials of either double-blind or open design have shown that selenium supplementation can enhance immune function and decrease the risk of developing certain infections in selenium-replete subjects, healthy adults and the elderly (Girodon et al 1999, Kiremidjian-Schumacher et al 1994, Roy et al 1994, Yu et al 1989).

The largest was a 3-year study of 20,847 people that showed that substituting conventional table salt with table salt fortified with sodium selenite significantly reduced the incidence of viral hepatitis compared with controls provided with normal table salt (Yu et al 1989).

Critically ill patients

Selenoproteins play an important role in the immunomodulation of critically ill patients, and low levels of plasma selenium have been associated with increased markers of oxidative stress, risk of organ failure and higher mortality rates. Clinical trials of selenium supplementation in critically ill patients however have produced mixed results. In a prospective, randomised, placebo-controlled, multicentre trial, critically ill patients received 1000 microgram of sodium selenite as a 30-min bolus injection, followed by 14 daily continuous infusions of 1000 microgram intravenously, or placebo. After 28 days, mortality rate was reduced in the treatment group to 42.4% compared with 56.7% in the placebo group. The mortality rate was significantly reduced in patients with septic shock or severe sepsis (Angstwurm et al 2007). In contrast, a prospective, multicentre, placebo-controlled, randomised, double-blind study of 60 patients with severe septic shock and infection found that the mortality rate of those receiving selenium supplementation (4000 microgram sodium selenite on the first day, 1000 microgram/day on the 9 following days) did not differ significantly from the placebo group (Heyland 2007). A prospective, single-centre study involving 40 septic ICU patients found that high-dose selenium supplementation (474, 316, 158 microgram/day, each for 3 consecutive days followed by a standard dose of 31.6 microgram/day given as sodium selenite) did not reduce oxidative damage or the requirement for renal replacement therapy (Mishra et al 2007). One possible explanation suggested for negative findings is sodium selenite having a direct pro-oxidant action in these patients (Forceville 2007).

Mood elevation and reduced anxiety

Considering that low dietary intakes of selenium have been linked with greater incidence of anxiety, depression and tiredness, several research groups have investigated whether higher dietary intakes or selenium supplementation will elevate mood and/or reduce anxiety. Currently, results are equivocal; however, it appears that selenium-replete individuals are most likely to respond to supplementation, if a response is observed.

An early double-blind, crossover study showed that short-term selenium supplementation (100 microgram/day for 5 weeks) significantly elevated mood and decreased anxiety, depression and tiredness, with effects most marked in people with low dietary intake (Benton & Cook 1991). A study of 30 selenium-replete men who were fed either a low (32.6 microgram/day) or a high (226.5 microgram/day) selenium diet for 15 weeks found that the mood of those with the higher selenium intake increased, whereas mood worsened with low intake (Finley & Penland 1998 as reported in Rayman 2005). Alternatively, another study involving 11 men of adequate selenium intake failed to show effects on mood when high (356 microgram/day) and low (13 microgram/day) selenium diets were followed for 99 days (Hawkes & Hornbostel 1996). Most recently, a large (n = 448), 2-year, randomised study also failed to find evidence that additional selenium enhanced mood or any of its subscales, despite significant increases in plasma selenium levels (Rayman et al 2006). This study compared the effects of 100, 200 or 300 microgram/day of selenium to placebo for effects on mood and QOL. Selenium supplementation was given as high-selenium yeast, SelenoPrecise™ (Pharma Nord, Vejle, Denmark).

Reducing morbidity in preterm babies

Preterm infants are born with slightly lower selenium and glutathione peroxidase concentrations than term infants and have low hepatic stores

of selenium. In very preterm infants, low selenium concentrations have been associated with an increased risk of chronic neonatal lung disease and retinopathy of prematurity (Darlow & Austin 2003). Although the full consequences of low selenium concentrations in this population are not fully known, observation from animal studies has found an association between selenium deficiency and increased susceptibility to oxidative lung injury. This has special significance for sick, very preterm infants as they are exposed to many possible sources of oxygen radical products, including high concentrations of inspired oxygen. A Cochrane review of three randomised studies that reported outcomes on 297 infants receiving selenium supplements and 290 control infants concluded that selenium supplementation in very preterm infants is associated with benefit in terms of a reduction in one or more episodes of late-onset sepsis, but is not associated with improved survival, a reduction in neonatal chronic lung disease or retinopathy of prematurity (Darlow & Austin 2003). It should be noted that most of the evidence derives from research conducted in New Zealand, a country with low soil and population selenium concentrations, and may not be readily translated to other populations. In one study, despite preterm infants having lower selenium levels compared to term infants, selenium levels did not correlate with chronic lung disease or septicaemia (Loui et al 2008).

OTHER USES

Used in combination with other antioxidants or administered intravenously, selenium has been used in pancreatitis and as adjunctive therapy in cancer patients.

Oral sodium selenite (350 microgram/m^2 body surface area) was given daily for 4–6 weeks to 52 patients with extensive, persistent or progressive lymphoedema from radiation and resulted in the majority experiencing some reduction in oedema (Micke et al 2002). A further study (Micke et al 2003) of 48 patients found that sodium selenite supplementation had a positive effect on secondary lymphoedema caused by radiation therapy alone or by irradiation after surgery. The group consisted of 12 patients with oedema of the arm and 36 with oedema of the head and neck region.

Cancer treatment often induces toxicity associated with the oxidative damage to normal cells. A Cochrane review of selenium in the prevention of side effects associated with cancer treatment (Dennert & Horneber 2006) found only two trials that met inclusion criteria. One study found lower incidence of recurrent erysipela infections of lymphoedematous upper limbs after breast cancer treatment in the selenium group, whilst preliminary results from another study suggest a lower incidence of diarrhoea in those receiving pelvic radiotherapy.

In an animal model, moderate selenium supplementation increased the total antioxidant activity leading to a lower generation of reactive oxygen metabolites, which helped to counteract the cardiotoxicity associated with the chemotherapeutic drug adriamycin (Danesi et al 2006).

DOSAGE RANGE

The Therapeutic Goods Act altered the allowed amount of selenium in listed products to be raised to 150 microgram. Supplements containing selenium carry the following caution on their label: 'This product contains selenium which is toxic in high doses. A daily dose of 150 microgram for adults of selenium from dietary supplements should not be exceeded.'

Australian RDI

Children
- 1–3 years: 25 microgram
- 4–8 years: 30 microgram
- 9–13 years: 50 microgram
- 14–18 years:
  Boys: 70 microgram
  Girls: 60 microgram

Adults
- Males >18 years: 70 microgram
- Females >18 years: 60 microgram
- Pregnancy: 65 microgram
- Lactation: 75 microgram

According to clinical studies

- Asthma: 100–200 microgram/day of sodium selenite.
- Cancer prophylaxis: 200 microgram/day selenium (supplied as 500 mg brewer's yeast).
- Infertility: 100 microgram/day.
- Mood disturbances: 100 microgram/day.
- Post myocardial infarction: selenium-rich yeast 100 microgram/day.
- Rheumatoid arthritis: 200 microgram/day.
- Autoimmune thyroiditis: 200 microgram/day sodium selenite.
- HIV-positive status: 80 microgram/day has been used but it is most likely that higher doses are required.

TOXICITY

Long-term ingestion of excessive levels of selenium (>1000 microgram/day) may produce fatigue, depression, arthritis, hair or fingernail loss, garlicky breath or body odour and gastrointestinal disorders or irritability (Fan & Kizer 1990).

ADVERSE REACTIONS

Nausea, vomiting, nail changes, irritability and fatigue have been reported.

The organic form of selenium found in high-selenium yeast is often preferred because it is less toxic.

The National Health and Medical Research Council of Australia states that selenium intake should not exceed 600 microgram/day.

SIGNIFICANT INTERACTIONS

Cisplatin

Selenium may reduce associated nephrotoxicity, myeloid suppression and weight loss, according to in vitro and in vivo tests (Camargo et al 2001, Ohkawa et al 1988) — potentially beneficial interaction.

Heavy metals (e.g. mercury, lead, arsenic, silver and cadmium)

Selenium reduces toxicity of heavy metals such as mercury, lead, arsenic, silver and cadmium by forming inert complexes — beneficial interaction.

CONTRAINDICATIONS AND PRECAUTIONS

Sensitivity to selenium.

PREGNANCY USE

Considered safe in usual dietary doses; safety at higher levels is unknown.

PRACTICE POINTS/PATIENT COUNSELLING

- Selenium is a trace element that is essential for health.
- Low selenium states have been associated with a variety of conditions such as cardiovascular disease, cancer, asthma, atopy, male subfertility, rheumatoid arthritis, depression and anxiety and compromised immune function.
- Studies have identified selenium deficiency in a significant number of people with the HIV infection and suggested a link between selenium levels and mortality rate.
- It is also involved in the detoxification of some heavy metals and xenobiotics.
- Selenium-enriched yeast is the safest way to supplement the diet, but other forms are also used.

PATIENTS' FAQs

What will this supplement do for me?

Selenium supplementation may reduce the risk of developing certain cancers and heart disease and help to improve a range of conditions such as rheumatoid arthritis, asthma, autoimmune thyroiditis, male subfertility, depression and anxiety.

When will it start to work?

If a protective effect is to occur with selenium against cancer or cardiovascular disease, the effect appears to develop slowly over several years' consistent intake.

Are there any safety issues?

High intakes of selenium above 1000 microgram/day have been associated with a number of adverse effects and should be avoided.

Shark cartilage

HISTORICAL NOTE Shark cartilage became a popular supplement in the 1980s, largely based around the claim that sharks rarely get cancer and therefore must have some protection against the disease. By 1995, the annual world market for shark-cartilage products exceeded US$30 million and dozens of shark cartilage products were available in retail stores and usually sold as food supplements (Ernst 1998). Over the past few decades, some progress has been made in identifying the various unusual compounds present in shark cartilage and it is clearly known that it contains some anti-angiogenic compounds, which increase resistance to tumours. Numerous shark cartilage derivatives and extracts are currently being investigated for effects on tumours including squalamine lactate, AE-941 and U-995. Previously, much work had been conducted with bovine cartilage, which also exhibits anti-angiogenic properties, although to a lesser extent.

BACKGROUND AND RELEVANT PHARMACOKINETICS

Although there has been some investigation into its actions and potential role as a therapeutic agent, little information is available about its pharmacokinetics.

CHEMICAL COMPONENTS

Shark cartilage is mainly composed of proteins, calcium, phosphorus, water, collagen and proteoglycans, chiefly chondroitin sulfates. Collagen imparts tensile strength and proteoglycans impart resilience to cartilage.

MAIN ACTIONS

Analgesic and anti-inflammatory

Both analgesic and anti-inflammatory activities have been reported for shark cartilage preparations in animal studies (Fontenele et al 1996, 1997). The mechanism of action is unknown; however, tests with the opioid antagonist naloxone have found it does not involve the opioid system (Fontenele et al 1997). One mechanism of action suggested is that shark cartilage significantly inhibits IL-1-induced PGE_2 synthesis (Pearson et al 2007).

Suppression of airway inflammation, by downregulating vascular endothelial growth factor, was demonstrated in an animal model, suggesting a possible novel therapeutic application to treat bronchial asthma. This research was carried out with a marine cartilage pharmaceutical formula called Neovastat (AE-941) (Lee et al 2005, Lee & Chung 2007).

There is also research indicating shark cartilage might be useful for some but not all inflammatory conditions. A number of different commercial shark cartilage extracts were tested and found to induce TH1 type inflammatory cytokines. In addition the acid extracts of shark cartilage tested produced higher amounts of TNF (alpha) than the other aqueous extracts. As well as stimulating a TH1 response, the cartilage extracts appeared to inhibit TH2 cells, which may be useful for hypersensitive individuals who would benefit from downregulation of the IgE response (Merly et al 2007).

Anti-angiogenic

Shark cartilage extract appears to block the two main pathways that contribute to the process of angiogenesis, matrix metalloproteases and the vascular endothelial growth factor signalling pathway (Anon 2004). The effect is due to several different constituents that have been isolated from shark cartilage and identified as exerting anti-angiogenic activity (Dupont et al 1998, Gonzalez et al 2001, Shen et al 2001, Sheu et al 1998, Zheng et al 2007, Bargahi & Rabbani-Chadegani 2008, Rabbani-Chadegani et al 2008) in various experimental models.

Antineoplastic effects

Due to its anti-angiogenic activity, shark cartilage has been investigated for antineoplastic effects. In one study, oral administration of powdered shark cartilage significantly delayed the development of papillary and solid tumours in a murine renal tumour model in experimental animals (Barber et al 2001). Shark cartilage proteoglycan was found to inhibit pancreatic carcinogenesis when administered to hamsters for 50 days (Kitahashi et al 2006).

Immunostimulant

A complex mixture of constituents is responsible for the immunostimulating properties of shark cartilage, according to in vitro research (Kralovec et al 2003). Of these, a protein fraction composed of two proteins with molecular weights of approximately 14 and 15 kDa has exhibited the most immunostimulatory effects (Hassan et al 2005).

OTHER ACTIONS

Antibiotic

Squalamine, isolated from dogfish shark cartilage, is a broad-spectrum antibiotic with activity against protozoa, fungi and both Gram-positive and Gram-negative bacteria (Moore 1993).

Antioxidant

Antioxidant activity has been demonstrated in vitro (Gomes et al 1996).

Fibrinolytic

Fibrinolytic activity of a shark cartilage extract was demonstrated in an in vitro study (Ratel et al 2005).

CLINICAL USE

Osteoarthritis

Based on its analgesic and anti-inflammatory activities, shark cartilage has been used to relieve symptoms in OA. To date, no clinical studies are available to determine its effectiveness; however, positive results have been obtained in several clinical studies for one of its constituents, chondroitin sulfate (see Chondroitin monograph for details).

Cancer

Shark cartilage is a popular supplement with cancer patients (Bernstein & Grasso 2001), although results from the few clinical trials conducted using shark cartilage in people with advanced cancers have generally produced negative findings suggesting no significant benefit.

One study of 60 people with advanced, previously treated cancer (breast, colorectal, lung, prostate, non-Hodgkin's lymphoma, brain) failed to demonstrate an effect for orally administered shark cartilage (1 g/kg) on tumour growth or QOL (Miller et al 1998). A larger study of 83 patients with advanced breast and colorectal cancers, which was published in 2005, also found that shark cartilage failed to improve survival or QOL (Loprinzi et al 2005). This study was a two-arm, randomised, placebo-controlled, double-blind, clinical trial. Of note, there was a high drop-out rate as only half the patients receiving shark cartilage powder continued with treatment beyond 1 month and only 10% were still using the treatment by 6 months. It was thought that gastrointestinal symptoms may have contributed to the poor patient compliance.

Clinical note — Angiogenesis and tumour growth
Angiogenesis is defined as the formation of new capillary blood vessels from existing microvessels and is a process regulated by inducers and inhibitors. It is critical for development, reproduction and repair and dominates many pathological conditions (Folkman 2003). In 1971, the hypothesis that tumour growth is angiogenesis-dependent was first proposed and since then, the study of angiogenesis inhibitors in cancer research has developed. It has now been demonstrated that solid tumours secrete angiogenic substances to set up an internal network of blood vessels to support further growth and there is a correlation between tumour microvessel density and the risk of metastases. In the absence of angiogenesis, tumour growth is restricted to a microscopic size and tumour cells do not shed into the circulation. Several clinical studies have been conducted with various anti-angiogenic therapies, generally indicating that despite an initial increase in tumour blood flow, long-term treatment causes total tumour blood flow to reach a steady state or to gradually decrease.

Several smaller preliminary studies have produced positive results, with some patients experiencing less tumour progression and weight loss, improved appetite or decreased pain (Couzin et al 2003). Unfortunately, details of these studies are difficult to locate and much remains unanswered, such as doses used, time frames for use and criteria for improvement.

Investigation with Neovastat (AE-941), a standardised shark cartilage extract, has produced more promising results and demonstrated inhibitory effects on the growth and metastasis of tumours; however, research has mainly been conducted in animal models (Hassan et al 2005). One clinical study conducted with Neovastat did report a significant survival advantage for the patients with unresectable stage IIIA, IIIB or IV non-small-cell lung cancers receiving treatment (Hassan et al 2005).

OTHER USES
There is one case report of a man with Kaposi's sarcoma whose lesion disappeared after taking shark cartilage (3.75–4.5 g/day for 9 months) (Hillman et al 2001).

DOSAGE RANGE
- Depending on the purity of the supplement, 500–4500 mg/day in divided doses.
- Various doses of cartilage have been used in different studies, ranging from 2.5 mg to 100 g/day (Simone et al 1998).

ADVERSE REACTIONS
A clinical study of 60 patients with advanced cancer reported the most common adverse reactions as gastrointestinal, such as nausea, vomiting and constipation (Miller et al 1998).

PRACTICE POINTS/PATIENT COUNSELLING
- Shark cartilage is mainly composed of calcium, phosphorus, water, collagen and proteoglycans, chiefly chondroitin sulfates.
- Anti-angiogenic, antineoplastic, immunostimulant and broad-spectrum antibiotic activities have been reported in preliminary studies.
- Both analgesic and anti-inflammatory activities have been reported for shark cartilage preparations in animal studies, most likely due to its chondroitin content. As a result, it is used to relieve symptoms in arthritic conditions.
- It is a popular supplement among cancer patients; however, the few clinical trials conducted so far with people with advanced cancers have generally produced negative results, suggesting no benefit.
- Its use is contraindicated in people with seafood allergy, and in pregnancy. Do not use 3 weeks before and 6 weeks after surgery, or in children or teenagers still experiencing growth.

SIGNIFICANT INTERACTIONS
Controlled studies and sufficient reliable information is not available to predict or determine interactions.

CONTRAINDICATIONS AND PRECAUTIONS
- Contraindicated in people with seafood allergy.
- Do not use 3 weeks before and 6 weeks after surgery, or in children or teenagers still experiencing growth.

Hypercalcaemia
Due to the high calcium content of this supplement, it should be used with caution in people with hypercalcaemia.

PREGNANCY USE
Although not scientifically investigated in this population, it is not recommended in pregnancy or lactation based on theoretical considerations.

PATIENTS' FAQs
What will this supplement do for me?
Shark cartilage has a number of different actions, such as anti-inflammatory, antibiotic, anti-tumour and pain-relieving effects. However, these have not been confirmed in controlled human studies. As a result, it is difficult to determine what effects will be experienced.
When will it start to work?
Due to the lack of human research, this is unknown.
Are there any safety issues?
Shark cartilage products are not to be used in people with seafood allergy or in pregnancy. They should not be used by children or teenagers still experiencing growth or 3 weeks before and for 6 weeks after surgery.

Shatavari

HISTORICAL NOTE There are approximately 300 species of 'asparagus' (derived from the Greek word for 'stalk' or 'shoot') including the popular European vegetable *Asparagus officinalis*. The medicinal use of *Asparagus racemosus* (shatavari) has been recorded in traditional systems of medicine such as Ayurveda, Unani and Siddh (Bopana & Saxena 2007). It is a different form of asparagus from the type commonly consumed as a food, which is *Asparagus officinalis*. Shatavari, meaning 'she who possesses a hundred husbands', is often considered an aphrodisiac (Sharma et al 2000) and a 'female tonic'. It is recommended in Ayurvedic texts for the prevention and treatment of gastric ulcers and dyspepsia; for threatened miscarriage and as a galactogogue; and is known as a 'rasayana' (a substance that promotes general physical and mental wellbeing by improving defence mechanisms and vitality) (Goyal et al 2003). Demand for shatavari in combination with destructive harvesting techniques and deforestation has resulted in the plant becoming 'endangered' in its natural habitat (Bopana & Saxena 2007).

OTHER NAMES

Asparagus bush, Inli-chedi, Kairuwa, Majjigegadde, Narbodh, Norkanto, Philli-gaddalu, Satavari, Satawar, Shatmuli, Shimaishadavari, Toala-gaddalu, wild asparagus

BOTANICAL NAME/FAMILY

Asparagus racemosus Willd. (family Asparagaceae [previously Liliaceae, subfamily Asparagae]) (Goyal et al 2003)

It should be differentiated from numerous other species reported in the scientific literature, including *A. acutifolius*, *A. adscendens*, *A. africanus*, *A. curillus*, *A. dumosus*, *A. filicinus*, *A. gonaclades*; and from *A. officinalis* (the stalks of which are consumed as a vegetable).

PLANT PART USED

Root

CHEMICAL COMPONENTS

Steroidal saponins (shatavarins VI-X); saponins (shatavarin I [or asparoside B], shatavarin IV [or asparinin B, a glycoside of sarsasapogenin], shatavarin V,

immunoside and schidigerasaponin D5 [or asparanin A] (Hayes et al 2008); isoflavones (Saxena & Chourasia 2001), racemofuran, asparagamine A and racemosol (Wiboonpun et al 2004), ascorbic acid (vitamin C) (Visavadiya & Narasimhacharya 2005). Sarsasapogenin and kaempferol have also been isolated from the woody portion of the roots (Bopana & Saxena 2007).

Steroidal saponins (racemosides A, B and C) have also been isolated from the fruit (Mandal et al 2006). Quercetin, rutin and hyperoside have been identified in the flowers and fruits, and diosgenin and quercetin-3 glucuronide in the leaves (Bopana & Saxena 2007).

MAIN ACTIONS

Adaptogenic (modulates stress response)

In Ayurvedic medicine herbs are usually used in combination and shatavari is used in approximately 64 Ayurvedic formulations. Research is usually conducted with herbal combinations containing shatavari, thereby making it difficult to ascertain the pharmacological and clinical effects of the individual herb (Bopana & Saxena 2007).

A polyherbal formula, known as EuMil, which contains standardised extracts of *A. racemosus* in combination with *Withania somnifera*, *Ocimum sanctum* and *Emblica officinalis*, ameliorates chronic stress-induced neurochemical perturbations and normalises noradrenaline, dopamine and 5-hydroxytryptamine (5HT) levels in animal experiments (Bhattacharya et al 2002). Other animal studies using EuMil have demonstrated attenuation of stress-induced glucose intolerance and immunosuppression, increased male sexual behaviour, and improvements in depression and cognitive dysfunction (Muruganandam et al 2002). These results were also found in a similar polyherbal known as Siotone, containing *A. racemosus*, *Withania somnifera*, *Ocimum sanctum*, *Tribulus terrestris* and shilajit (a composted plant exudate high in minerals) (Bhattacharya et al 2000). Whether these results are consistent in humans, and which herbs they are attributed to, has not yet been established.

Digestive effects

Early studies suggested that shatavari could improve digestion by increasing levels of amylase and lipase (Dange et al 1969). A small study of 8 healthy males using a cross-over design found that oral administration of dried shatavari root had similar effects on gastric emptying time to the antiemetic drug metoclopramide, a synthetic dopamine antagonist which is used in dyspepsia to promote gastric emptying (Dalvi et al 1990). Animal experiments using oral doses of shatavari have also reversed the effects of cisplatin on gastric emptying, while normalising cisplatin-induced intestinal hypermotility (Rege et al 1999).

Antiulcerogenic

Antiulcerogenic activity comparable to a standard antiulcer drug Ranitidine (30 mg/kg/day orally) has been demonstrated in rats. Treatment with a crude extract of shatavari (100 mg/kg/day orally) for fifteen days significantly reduced indomethacin (NSAID) induced ulceration when compared with the control group. The effect appeared to be related to an inhibition of hydrochloric acid and protection of the gastric mucosa (Bhatnagar & Sisodia 2006). Early studies demonstrated that shatavari could relieve pain and burning due to duodenal ulceration and proposed that these effects may be due to: an increase in the secretion and viscosity of gastric mucus; formation of a shatavari–mucus complex at the base of the ulcer, providing protection from corrosive agents; prolongation of the life span of mucosal cells and/or a cytoprotective effect similar to that of prostaglandins (Goyal et al 2003). Some of these hypotheses have been supported by further research. The antiulcerogenic effect of oral administration of a methanolic extract of fresh shatavari root (25–100 mg/kg) twice daily for 5 days was studied on different gastroduodenal ulcer models in rats (Sairam et al 2003). Doses of 50 mg/kg twice daily demonstrated significant protection against acute gastric ulceration induced by 'cold restraint stress, pyloric ligation, aspirin plus pyloric ligation, and duodenal ulcers induced by cysteamine' and promoted healing of acetic acid-induced chronic gastric ulceration after 10 days of treatment. An effect was not demonstrated for aspirin- or ethanol-induced gastric ulcers. The effect was believed to be due to an increase in mucus secretion, cellular mucus, the life span of cells, as well as a significant anti-oxidant effect (Sairam et al 2003).

Immunomodulation

In in vitro studies *A. racemosus* increased the phagocytic and killing capacity of macrophages in a dose dependent manner (up to 200 mg/kg) (Rege & Dahanukar 1993). Experimental models in mice have demonstrated the immunostimulating properties of *A. racemosus,* inhibiting the leucopaenia associated with cyclophosphamide by inducing leucocytosis with neutrophilia (Thatte & Dahanukar 1988). Animal studies have demonstrated that oral administration of *A. racemosus* inhibited some of the deleterious effects of ochratoxin A suppression of chemotactic activity and production of IL-1 and TNF-alpha by macropahges, and also induced excess production of TNF-alpha in animals that did not receive ochratoxin A (Dhuley 1997). It also appears to reduce intraperitoneal adhesions induced by caecal rubbing by increasing the activity of macrophages (Rege et al 1989), and may act as an immunoadjuvant in animals immunised with diphtheria, tetanus, pertussis (DTP) vaccine, increasing antibody titres to *Bordetella pertussis* and providing improved immunoprotection on challenge (Gautam et al 2004).

Antibacterial

In vitro studies using different concentrations (50, 100, 150 microgram/mL) of the methanolic extract of shatavari root demonstrated considerable antibacterial efficacy against: *Escherichia coli*, *Shigella dysenteriae*, *Shigella sonnei*, *Shigella flexneri*, *Vibrio cholerae*, *Salmonella typhi*, *Salmonella typhimurium*, *Pseudomonas putida*, *Bacillus subtilis* and *Staphylococcus*

aureus (Mandal et al 2000b). A constituent of *A. racemosus* fruit, racemoside A, exhibits potent anti-leishmanial activity (Dutta et al 2007) against the dangerous visceral form of leishmaniasis.

Hormonal activity

The steroidal saponins (shatavarins) contained in *A. racemosus* may help explain some of the hormonal effects demonstrated in animal models. An alcoholic extract of Shatavari root (300 mg/kg bodyweight) was administered orally to pregnant female albino rats during days 1–15 of gestation. The results suggested an oestrogenic effect on the mammary glands and genital organs (Pandey et al 2005). Tests with animal models indicate shatavari competitively blocks the effect of oxytocin, thereby inhibiting oxytocin-induced uterine contraction in rabbits, rats and guinea pigs (Gaitonde & Jetmalani 1969). This action appears to be due to the asparagamine, a polycyclic alkaloid (Sekine et al 1994).

Galactagogue

Galactagogue activity has been demonstrated in animal models (Patel & Kanitkar 1969, Sabnis et al 1968). One study of weaning rats found shatavari treatment increased the weight of mammary glands, inhibited involution of lobulo-alveolar tissue and maintained milk secretion (Sabnis et al 1968). It has been proposed that this effect may be due to the action of released corticoids and prolactin (Goyal et al 2003).

A randomised placebo-controlled trial of 64 lactating women in India found a herbal combination galactagogue formula (including shatavari 15%) had no effect on prolactin levels or lactation (Sharma et al 1996). Results were comparable for both treatment and placebo groups with prolactin levels declining after therapy; a similar frequency and volume of supplementary milk feeds; and similar weight gain in infants. Drop out rates were high (17.2%) and the majority of women were using supplemental feeding, which may have affected the results, however results remained comparable when stratified for exclusive and non-exclusive breast feeding. Since shatavari was only one component of the formula, it is possible that the treatment dose was too low to have an effect and further clinical trials are required using singular treatment with shatavari.

Antidiarrhoeal

Ethanol and aqueous extracts (200 mg/kg) of shatavari root have been shown to inhibit castor oil induced diarrhoea, and PGE_2 induced enteropooling (excessive secretion of water and electrolytes); and reduced gastrointestinal motility in rats (Venkatesan et al 2005). The anti-diarrhoeal activity described is similar to the drug loperamide.

Antioxidant

A. racemosus contains known antioxidant compounds including ascorbic acid, polyphenols and flavonoids (Visavadiya & Narasimhacharya 2005). Antioxidant properties have also been identified for racemofuran, asparagamine A and racemosol (Wiboonpun et al 2004). In vitro experiments have demonstrated antioxidant effects comparable to that of glutathione and ascorbic acid in inhibiting lipid peroxidation and protein oxidation (Kamat et al 2000). Animal models confirmed the inhibition of lipid peroxidation and also showed an increase in antioxidant enzymes (superoxide dismutase, catalase) and ascorbic acid (Bhatnagar et al 2005, Visavadiya & Narasimhacharya 2005).

Cardiovascular effects

Studies using different animal models indicate various effects on heart function. Goyal et al (2003) found lower doses of shatavari root produce a positive inotropic and chronotropic effect on frog's heart, with higher doses causing cardiac arrest. The extract was also found to produce hypotension in cats (attenuated by atropine) indicating a cholinergic mechanism; and a slight increase in bleeding time in rabbits (Goyal et al 2003).

Animal studies have also demonstrated that shatavari root powder added to the feed (at a rate of 5 and 10%) provided to hypercholesterolaemic rats significantly reduced the plasma and hepatic lipid (cholesterol) levels in a dose dependent manner and also decreased hepatic lipid peroxidation (Visavadiya & Narasimhacharya 2005). This effect was likely due to decreased absorption of exogenous cholesterol and increased conversion of endogenous cholesterol to bile acids for excretion. However, these doses may not be feasible in human studies.

Hepatoprotective

An alcoholic extract of shatavari root significantly reduces elevated levels of alanine transaminase (ALT), aspartate transaminase (AST) and alkaline phosphatase (ALP) in vivo (Muruganandan et al 2000).

Neuroprotective

Oxidative stress and excitotoxicity are considered to be major mechanisms of neuronal cell death in neurodegenerative disorders such as Alzheimer's and Parkinson's diseases. Experimental studies have demonstrated that shatavari extract may attenuate oxidative damage, elevating glutathione peroxidase (GPx) activity and glutathione (GSH) content; and could result in a protective effect on kainic acid (KA)-induced excitotoxicity (Parihar & Hemnani 2004).

Antidepressant

Antidepressant activity has been demonstrated in vivo. A methanolic extract of *A. racemosus* root (MAR) (standardised to saponins 62.2% w/w) was given to rats in doses of 100, 200 and 400 mg/kg daily for 7 days. The results show that MAR decreased immobility in forced swim tests (FST) and increased avoidance response in learned helplessness tests (LH), indicating antidepressant activity. Effects were thought to be mediated through the serotonergic and noradrenergic systems, and augmentation of antioxidant defenses (Singh et al 2008).

Antineoplastic

An extract of shatavari root has been reported to reduce the incidence of DMBA (7,12-dimethyl benz(a)anthracene)-induced mammary cancer in

female rats (Rao 1981). The effect is thought to be due to properties that render the mammary epithelium refractory to the carcinogen. Clinical implications remain to be tested.

Antilithic

An ethanolic extract of shatavari inhibited experimentally induced urinary lithiasis (stone formation) in vivo (Christina et al 2005). Administration of shatavari reduced elevated urinary concentrations of calcium, oxalate and phosphate, which contribute to stone formation, and increased urinary concentration of magnesium, which is thought to be protective. Elevated serum creatinine was also reduced.

Antitussive

Strong antitussive activity has been demonstrated in animal models. A methanolic extract of shatavari root (200 and 400 mg/kg orally) showed significant antitussive activity on sulfur dioxide-induced cough in mice. The dose dependent cough inhibition (40.0 and 58.5%, respectively) was comparable to that of 10–20 mg/kg codeine phosphate (36.0 and 55.4%, respectively) (Mandal et al 2000a).

CLINICAL USE

Shatavari has not been subjected to extensive clinical testing so most information is derived from traditional use and in vivo experiments.

Stress

Currently, evidence to support the use of shatavari as a sole agent for reducing the deleterious effects of stress on the body is limited. Animal studies using polyherbal formulations such as EuMil (Bhattacharya et al 2002, Muruganandam et al 2002) and Siotone (Bhattacharya et al 2000) have shown some promise, but further research is required.

Dyspepsia

Shatavari root is used in Ayurvedic medicine for the treatment of dyspepsia. This may in part be due to improved digestion via increased levels of amylase and lipase (Dange et al 1969), and its ability to promote gastric emptying in a manner comparable to metoclopramide (Goyal et al 2003), and to normalise intestinal hypermotility (Rege et al 1999).

Gastrointestinal ulcers

In animal models, shatavari has been shown to reduce the incidence and increase the rate of healing of ulcers; while also relieving the pain and burning associated with duodenal ulceration (Goyal et al 2003). Antiulcerogenic activity of a crude extract of shatavari (100 mg/kg/day orally) has been found to be comparable to a standard antiulcer drug ranitidine (30 mg/kg/day orally) in rats. The effect may be related to an inhibition of hydrochloric acid and protection of the gastric mucosa (Bhatnagar & Sisodia 2006).

Prevention of infection

In vitro and animal experiments have demonstrated positive effects on immunity (particularly on the activity of macrophages) (Rege et al 1989, Rege & Dahanukar 1993) as well as antibacterial effects against *Escherichia coli*, *Shigella dysenteriae*, *Shigella sonnei*, *Shigella flexneri*, *Vibrio cholerae*, *Salmonella typhi*, *Salmonella typhimurium*, *Pseudomonas putida*, *Bacillus subtilis* and *Staphylococcus aureus* (Mandal et al 2000b). Further research is required in clinical trials to ascertain whether these effects can be demonstrated in humans.

OTHER USES

Hormonal disturbances in women

Traditionally shatavari is used as a 'rejuvenative tonic' for females and for lowered libido and infertility in both sexes. Due to its oestrogenic effects it is often used by herbalists for the treatment of conditions related to low oestrogen including some presentations of PMS and menopause; and to re-establish normal ovulation and menstruation patterns (Trickey 2003). Human trials have demonstrated positive results for dysfunctional uterine bleeding, dysmenorrhoea, PMS and menopausal symptoms, however these studies used the polyherbal formulations EveCare® and Menosan which contain *A. racemosus* (Bopana & Saxena 2007) so it is difficult to ascertain the role played by shatavari alone.

Promoting lactation

Shatavari root is used traditionally in Ayurvedic medicine to increase milk production and secretion during lactation. Early animal studies support this use (Sabnis et al 1968, Patel & Kanitkar 1969), however only one clinical trial has been conducted involving a polyherbal formulation containing shatavari (15%) which failed to find a significant effect (Sharma et al 1996).

Polyherbal combinations including *A. racemosus* have shown more promise. Ricalex (Aphali Pharmaceutical Ltd, Ahmednagar) (Joglekar et al 1967) and Lactare (TIK Pharma, Chennai) have been shown to increase milk production in women complaining of deficient milk secretion (Goyal et al 2003). However, it would appear that this effect may be due to other herbs contained in the formulas or to a synergistic interaction between the herbs, rather than the effect of shatavari alone.

Diarrhoea

Shatavari root is used traditionally in Ayurvedic medicine for the treatment of diarrhoea and dysentery. Ethanol and aqueous extracts of shatavari root demonstrate effects similar to loperamide by inhibiting diarrhoea, enteropooling and gastrointestinal motility (Venkatesan et al 2005). Human studies are warranted to confirm these effects.

DOSAGE RANGE

Fluid extract (1:2): 30–60 mL/week (Australian manufacturer's recommendations).

ADVERSE REACTIONS

No significant adverse events or biochemical liver dysfunction was noted in a randomised controlled trial of shatavari (Sharma et al 1996). Due to the saponin content, gastric irritation may occur in some individuals.

SIGNIFICANT INTERACTIONS

As controlled studies are not available, interactions are currently speculative and based on evidence of pharmacological activity. No evidence could be located that suggested any negative drug interactions.

Metoclopramide

As shatavari root was found in animal studies to have similar effects on gastric emptying time to the antiemetic drug metoclopramide (a synthetic dopamine antagonist), an additive effect is possible (Dalvi et al 1990).

Diphtheria, tetanus, pertussis (DTP) vaccine

Experimental studies have suggested a possible immunoadjuvant effect in animals immunised with diphtheria, tetanus, pertussis (DTP) vaccine, increasing antibody titres to *Bordetella pertussis* and providing improved immunoprotection on challenge (Gautam et al 2004). Beneficial effects possible.

CONTRAINDICATIONS AND PRECAUTIONS

No toxic effects or mortality have been observed with doses ranging from 50 mg/kg to 1 g/kg for 4 weeks, and acute and subacute (15–30 day) toxicity studies have not detected any changes in results of vital organ function tests. The LD50 is >1 g/kg (Rege et al 1999).

As inhibition of hydrochloric acid has been proposed as a possible factor contributing to the antiulcer effects of shatavari (Bhatnagar & Sisodia 2006), those with hypochlorhydria may need to be observed.

Herbs with theoretical oestrogenic effects may not be suitable for those with or at risk of oestrogen dependent tumours. The clinical significance however is unclear.

The Commission E has approved the use of *A. officinalis* root in irrigation therapy for inflammatory diseases of the urinary tract and for prevention of kidney stones, however this should be avoided if oedema exists due to functional heart or kidney disorders (Blumenthal et al 2000). Similar cautions might be expected for *A. racemosus*.

PREGNANCY USE

Although shatavari has been used traditionally to promote conception and for threatened miscarriage, teratogenicity has recently been demonstrated in rats at doses of 100 mg/kg/day for 60 days (Goel et al 2006). Caution should be exercised in pregnancy until more is known about effects in humans. While the traditional use of shatavari in breast feeding has not been supported by human studies (Sharma et al 1996), no significant side effects were reported in clinical trials.

PATIENTS' FAQs

What will this herb do for me?

It is difficult to determine what effects shatavari will display when used as a sole treatment, as it is most often tested as part of a polyherbal combination formula. The herbal combinations containing shatavari have a myriad of uses, such as improving digestion, promoting lactation and increasing libido. Shatavari root is used traditionally in Ayurvedic medicine for the treatment of diarrhoea and dysentery, gastric ulcers and dyspepsia, threatened miscarriage and as a galactogogue.

When will it start to work?

This is difficult to estimate as the majority of human trials have been conducted with polyherbal preparations containing shatavari and not with shatavari as a sole treatment.

Are there any safety issues?

Caution should be exercised in pregnancy until more is known about the potential teratogenic effects.

PRACTICE POINTS/PATIENT COUNSELLING

- In Ayurvedic medicine shatavari is used in approximately 64 Ayurvedic polyherbal formulations. As much of the current research focuses on these preparations it is difficult to ascertain the pharmacological and clinical effects of the individual herb.
- Shatavari may exert beneficial effects on digestion by increasing levels of lipase and amylase, promoting gastric emptying, normalising intestinal motility and protecting against ulceration.
- Shatavari is used, often in combination with other herbs, to improve milk production in lactating women, although human data supporting this effect are currently lacking.
- Animal models suggest that the steroidal saponins contained in *A. racemosus* may exert some hormonal effects which may account for its reputation as a female tonic and aphrodisiac.
- As teratogenicity has recently been demonstrated in rats, caution should be exercised in pregnancy until more is known about effects in humans.
- Demand for shatavari in combination with destructive harvesting techniques and deforestation has resulted in the plant becoming 'endangered' in its natural habitat.

Slippery elm

HISTORICAL NOTE The dried inner bark of the slippery elm tree was a popular remedy used by many Native American tribes, and subsequently taken up by European settlers. It was mixed with water and applied topically to treat wounds, bruises and skin irritations, and used internally for sore throat, coughs and gastrointestinal conditions. When mixed with milk, it was used as a nutritious gruel for children and convalescents. It also gained a reputation as an effective wound healer among soldiers during the American Civil War. From 1820 until 1960, it was listed in the US Pharmacopeia as a demulcent, emollient and antitussive (Ulbricht & Basch 2005). The name 'slippery elm' refers to the slippery consistency of the inner bark when it comes into contact with water.

COMMON NAME
Slippery elm

OTHER NAMES
American elm, Indian elm, moose elm, red elm, sweet elm, winged elm

BOTANICAL NAME/FAMILY
Ulmus fulvus or *Ulmus rubra* (family Ulmaceae)

According to current botanical nomenclature, it should now be referred to as *Ulmus rubra*.

PLANT PART USED
Dried inner bark

CHEMICAL COMPONENTS
The inner bark chiefly contains mucilage (various hexoses, pentoses, methylpentoses), glucose, polyuronides, tannins, galacturonic acid, L-rhamnose, D-galactose, starches, fat, phytosterols, sesquiterpenes and cholesterol (Beveridge et al 1969, Duke 2003, IM Gateway Database 2003, Newell et al 1996). The bark provides 2740 kilocalories

Clinical note — Mucilages
Mucilages are hydrophilic structures, capable of trapping water, which causes them to swell in size and develop a gel-like consistency. The gels tend to have soothing properties and can be broken down by bowel flora when taken internally (Mills & Bone 2000). Mucilages are known to have beneficial effects on burns, wounds and ulcers when applied externally and on gastric inflammation, irritations and diarrhoea when taken internally.

per kilogram. It contains a variety of nutritional factors such as glucose, calcium, iron, vitamin C, thiamine, zinc, magnesium and potassium, providing support for its traditional use as a nutritious gruel.

MAIN ACTIONS

The pharmacological actions of slippery elm have not been significantly investigated in clinical studies. Therefore, information is generally based on what is known about key constituents found within the herb.

Soothes irritated and inflamed tissue

The large amount of mucilage found in slippery elm bark will coat the surface of mucous membranes or wounds and sores when it comes in contact with water, and form a gel-like layer. Laboratory research has shown that mucilaginous medicinal plants, such as slippery elm, can decrease local irritation in acute gastritis.

Nutritive demulcent

A number of constituents, such as starch, glucose, calcium, iron, vitamin C, thiamine, zinc, magnesium and potassium are present in slippery elm, making it a source of many nutritional factors (Duke 2003).

Antioxidant

In vitro studies show a free radical scavenging activity that may relate to its anti-inflammatory action (Langmead et al 2002).

CLINICAL USE

The therapeutic effectiveness of slippery elm has not been significantly investigated under clinical trial conditions, so evidence is derived from traditional, in vitro and animal studies.

Gastrointestinal conditions

Based on traditional evidence, slippery elm is taken internally to relieve the symptoms of gastritis, acid dyspepsia, gastric reflux, peptic ulcers, irritable bowel syndrome and Crohn's disease.

It is widely accepted that the mucilage acts as a barrier against the damaging effects of stomach acid on the oesophagus and may also exert mild anti-inflammatory activity locally. Currently, clinical research is not available to determine the effectiveness of slippery elm in these conditions; however, anecdotally the treatment appears to be very successful and patients report rapid improvement in upper gastrointestinal symptoms.

Clinical note — Essiac tea
Slippery elm is one of the key ingredients in Essiac tea, which was reportedly developed by the Ojibwa tribe of Canada and named after an Ontario nurse (Rene Caisse) to whom the formula for the herbal tea was given by an Ojibwa healer in 1922 (Smith & Boon 1999). It is used to treat a variety of diverse conditions, such as allergies, hypertension and osteoporosis. The tea is made up of a mixture of four herbs, *Arctium lappa* (burdock root), *Rumex acetosella* (sheep sorrel), *Ulmus rubra* (slippery elm) and *Rheum officinale* (rhubarb) and is considered to possess antioxidant and, possibly, anticancer activities (Leonard et al 2006). As a result, it is used widely by North American cancer patients during chemo- and radiotherapies (Cheung et al 2005) for reduction in symptoms associated with cancer treatment and as a possible adjunctive treatment. In vitro tests with Essiac have identified anticancer activity, although its effects in vivo are controversial and evidence of efficacy is anecdotal (Leonard et al 2006). A recent study demonstrated that Essiac tea effectively scavenges several types of radicals and possesses DNA-protective effects (Leonard et al 2006). A retrospective cohort study of 510 women with breast cancer found that Essiac did not improve quality-of-life scores or mood (Zick et al 2006). Daily doses of Essiac ranged from 12 to 114 mL with the average dose being 43.6 mL, corresponding to doses recommended on popular products. Duration of treatment ranged from 1 to 28 months, with the average being 11.1 months. The formula was well tolerated with only 2 women reporting minor adverse events, whilst many women reported beneficial effects.

Solid dose tablets and capsules are used in the treatment of diarrhoea when it is believed the fibre will slow down gastric transit time and act as a bulking agent. Although clinical studies are not available to determine its effectiveness, the high mucilaginous content and presence of tannins in the herb provide a theoretical basis for its use.

Dermatitis and wounds

Slippery elm has also been used as a topical agent to soothe irritated and/or inflamed skin conditions, wounds and burns and to draw out boils and abscesses (Fisher & Painter 1996). When applied, it forms a protective gel-like layer, which is considered to have soothing properties.

OTHER USES

Traditionally, slippery elm is used to treat bronchitis, cystitis and intestinal parasites. Externally, it has been used to treat gout, inflamed joints and toothache (Fisher & Painter 1996).

DOSAGE RANGE

Owing to insufficient data available from clinical studies, doses have been derived from Australian manufacturers' recommendations.

Gastrointestinal symptoms

- One to two capsules containing 150 mg of slippery elm before meals.
- Fluid extract (60%): 5 mL three times daily.
- Half a teaspoon of slippery elm bark powder is mixed with one cup of hot water and taken up to three times daily. For added flavouring, cinnamon or nutmeg can be added.

External use

- Mix the coarse powdered bark with enough boiling water to make a paste and use as a poultice (Hoffman 1983).

TOXICITY

Insufficient reliable information is available.

ADVERSE REACTIONS

Insufficient reliable information is available.

SIGNIFICANT INTERACTIONS

Controlled studies are unavailable, but interactions are theoretically possible with some medicines.

Since slippery elm forms an inert barrier over the gastrointestinal lining, it may theoretically alter the rate and/or extent of absorption of medicines with a narrow therapeutic range (e.g. barbiturates, digoxin, lithium, phenytoin, warfarin). The clinical significance of this is unclear. Separate doses by 2 h.

CONTRAINDICATIONS AND PRECAUTIONS

Insufficient reliable information is available.

PREGNANCY USE

It is likely to be safe, but safety is still to be established.

PATIENTS' FAQs

What will this herb do for me?

The inner bark of slippery elm is highly mucilaginous, meaning that it forms a thick gel-like substance when combined with water. Traditionally, it has been used internally to relieve symptoms of dyspepsia and inflamed bowel conditions and topically to soothe irritated skin and promote wound healing.

When will it start to work?

Whether used internally for upper gastrointestinal symptoms (such as reflux and dyspepsia) or applied topically to irritated skin, it should theoretically provide quick symptomatic relief; however, research to confirm this is not available.

Are there any safety issues?

Although slippery elm has not been scientifically investigated, the Federal drug agency (FDA) in the USA has approved it as a safe demulcent substance.

PRACTICE POINTS/PATIENT COUNSELLING

- Slippery elm inner bark is a highly mucilaginous substance, which has been traditionally used as a topical application to soothe irritated and inflamed skin conditions and promote wound healing.
- It is used internally to soothe an irritated throat and is often combined with antiseptic herbs.
- Slippery elm is used to provide symptomatic relief in acid dyspepsia, gastrointestinal reflux and inflammatory bowel diseases, but has not been scientifically studied to any significant extent.
- Overall, slippery elm has not been significantly investigated in clinical studies, so most information is derived from traditional sources.

Soy

HISTORICAL NOTE Soybeans were one of the first crops grown by humans and have been consumed for approximately 5000 years in China where they are regarded as both a food and a medicine. During the Chou dynasty 1134–246 BC fermentation techniques were developed to produce tempeh, miso and tamari soy sauce, with tofu being invented around the second century BC. Soy first reached the West as imported soy sauce, and soybean cultivation began in the 1770s, primarily for animal feed. It was not until World War I that soy became a significant crop for human consumption (Natural Standard Patient Monograph 2005). Soy protein was first produced in the 1930s for its functional properties and used as a pigment binder for paper, a foam for fire extinguishers and a fibre for making artificial silk before being used as a food supplement in the 1960s.

COMMON NAME
Glycine max

OTHER NAMES
Glycine soja, dolichos soja, glycine gracilis, glycine hispida, phaseolus max, soja hispida, soja max

BOTANICAL NAME/FAMILY
Glycine max (family Fabaceae [Leguminosae])

PLANT PART USED
Bean

CHEMICAL COMPONENTS
Soybeans are a high-nutrient food containing up to 50% protein. Soy protein contains all of the essential amino acids in sufficient quantities to act as a sole protein source with methionine (a precursor of homocysteine) being the limiting amino acid (Young 1991).

Soy is a major food source of phyto-oestrogens (isoflavones and lignans), with each gram of soy protein containing approximately 1–3 mg of isoflavones, including glycosides of genistein, daidzein and glycitein (Erdman 2000). Soy also contains the lignans secoisolariciresinol, matairesinol, syringaresinol, lariciresinol, isolariciresinol and pinoresinol (Penalvo et al 2004), as well as soy lecithin (a phospholipid containing linoleic and linolenic acid), vitamin E (in its four isomeric forms as alpha, beta, gamma and delta-tocopherol), oligosaccharides, the phytosterols beta-sitosterol, campesterol and stigmasterol, phytates and protease inhibitors, inositol hexaphosphate, saponins and oligosaccharides (Mazur et al 1998, Tripathi & Misra 2005).

MAIN ACTIONS
Daidzein, an isoflavone found in soy, is metabolised to the more metabolically active equol and O-desmethylangolensin (O-DMA) by as yet unspecified intestinal bacteria. Following soy or daidzein consumption, approximately 30–50% of the human population produce equol, and approximately 80–90% produce O-DMA; however, the significance of this is uncertain, despite some studies suggesting that the ability to produce equol and O-DMA may be associated with reduced risk of certain diseases, including breast and prostate cancers (Atkinson et al 2005).

Predicting the effects of isoflavones in vivo is difficult because the route of administration, chemical form of the phyto-oestrogen, its metabolism, bioavailability, half-life, timing and level of exposure, intrinsic oestrogenic state and non-hormonal secondary mediated actions of isoflavones may all influence their biological and clinical effects (Setchell & Cassidy 1999) and the mechanisms for the clinical effects of soy are yet to be fully evaluated (Balk et al 2005, Setchell & Cassidy 1999).

Oestrogen receptor/hormonal modulation
Soy isoflavones and lignans share structural similarities with oestrogen and are referred to as phyto-oestrogens and/or selective oestrogen receptor modulators (Sliva 2005). Soy isoflavones have weak oestrogenic activity. The order of activity in in vivo assays is glycitein > genistein > daidzein (PDRHealth 2004). Soy isoflavone glycosides bind weakly to both oestrogen receptors, with the binding affinity of genistein, dihydrogenistein and equol being comparable to the binding affinity of 17-beta-oestradiol (Morito et al 2001).

Isoflavones have complex actions that may be tissue specific and may act as partial oestrogen agonists and antagonists, as well as having non-classical effects on plasma membranes and cell signalling pathways (Setchell & Cassidy 1999).

The oestrogenic effects of soy are postulated to contribute to protective effects against cardiovascular disease, cancer and menopausal symptoms. Although a review of 861 studies on the effects of phyto-oestrogens suggests that they are indeed biologically active in humans (Knight & Eden 1996), major gaps in knowledge still exist regarding the effects of phyto-oestrogen supplements on bone diseases, various cancers, menopausal symptoms and cognitive function (Lu et al 2001, Stark & Madar 2002). Interestingly, soy has a greater affinity for the oestrogen beta-receptor than the alpha-receptor. The beta-receptor is found in brain, bone, bladder and vascular epithelia, tissues in which isoflavones purportedly have activity (Setchell & Cassidy 1999).

Genistein has been found to have an oestrogen-like effect on the serum lipid profile (Yildiz et al 2005); however, in a double-blind, placebo-controlled trial in 40 healthy postmenopausal women aged 50–75 years, 40 g of soy protein containing 118 mg isoflavones did not produce biologically significant oestrogenic effects on coagulation, fibrinolysis or endothelial function (Teede et al 2005). In another 12-month, double-blind, randomised trial of soy protein containing 99 mg isoflavones/day in 202 postmenopausal women, systolic blood pressure (SBP) and diastolic blood pressure (DBP) decreased and endothelial function improved in the equol producers, with increased blood pressure and deterioration in endothelial function seen in the equol non-producers (Kreijkamp-Kaspers et al 2005).

A review of 50 RCTs of soy and endocrine function suggest that there are no consistent statistically significant effects of soy on follicle stimulating hormone (FSH) or thyroid stimulating hormone (TSH) levels or on oestradiol levels at the follicular phase, or on menstrual cycle length.

Hormonal effects in men
Whether soy products have a significant effect on testosterone levels in healthy males remains uncertain (Balk et al 2005); however, the results of two trials suggest it may. One study found that soy protein powder decreases serum testosterone levels in healthy men and acts as an oestrogen receptor agonist (Goodin et al 2007) while another small study of 99 male partners of subfertile couples identified that a higher intake of soy foods and soy isoflavones was associated with a lower sperm concentration while being unrelated to sperm motility, sperm morphology or ejaculate volume (Chavarro et al 2008).

Cardiovascular disease

There are many potential mechanisms by which soy isoflavones may improve cardiovascular outcomes, including reduction in total cholesterol, LDL, HDL, triglycerides, lipoprotein A, blood pressure, C-reactive protein, homocysteine, endothelial function, systemic artery compliance and oxidised LDL (Balk et al 2005). Further mechanisms include an inhibition of pro-inflammatory cytokines, cell adhesion proteins and inducible nitric oxide production, potential reduction in the susceptibility of the LDL particle to oxidation, inhibition of platelet aggregation and an improvement in vascular reactivity (Rimbach et al 2008).

Consumption of soy protein may further produce cardiovascular benefits through multiple mechanisms, including the low methionine content reducing serum homocysteine concentration (Nagata et al 2003), reduction of the insulin/glucagon ratio (Sanchez & Hubbard 1991), down-regulation of the hepatic transcription factor sterol regulatory element binding protein-1, which in turn reduces lipotoxicity in the liver (Torres et al 2006), regulation of hepatic lipid metabolism through upregulation of LDL receptors and increase in bile acid secretion (Potter 1995), reducing hepatic fatty acid and triglyceride biosynthesis and increasing fatty acid oxidation (Tovar et al 2005), preventing the transfer of fatty acids to extra adipose tissues by increasing the adipocyte hormone adiponectin (Nagasawa et al 2003), and increasing bile acid secretion and bacterial conversion of cholesterol to the non-absorbable coprostanol (Huff & Carroll 1980). Soy protein peptides may also act to decrease intestinal cholesterol absorption and bile acid uptake, reduce aortic accumulation of cholesterol esters and suppress food intake and gastric emptying by increasing cholecystokinin, and inhibiting angiotensin-converting enzyme (Torres et al 2006). An RCT, however, suggests that decreasing vascular inflammation and homocysteine concentration are unlikely to be mechanisms by which soy consumption reduces coronary heart disease risk (Greany et al 2008).

A review by the North American Menopause Society suggests that the most convincing health effects of soy can be attributed to the actions of isoflavones on lipids, with studies finding statistically significant reductions in LDL and triglycerides, as well as increases in HDL (Greenwood et al 2000). This is supported by many epidemiological studies reporting an association between a high intake of soy isoflavones and reduced cardiovascular risk (Kokubo et al 2007). Further support comes from clinical trials with a recent meta-analysis of 11 studies reporting that soy isoflavones significantly reduced serum total and LDL cholesterol but did not change HDL cholesterol and triglycerides and that soy protein containing enriched or depleted isoflavones also significantly improved lipid profiles with reductions in LDL cholesterol being larger in hypercholesterolaemic than in normocholesterolaemic subjects (Taku et al 2007). Furthermore, recent evidence indicates that soy consumption may improve glycaemic control and cardiovascular risk markers in postmenopausal women (Atteritano et al 2007, Azadbakht et al 2007).

It is unclear how soy exerts its beneficial effects on lipid metabolism or exactly which components are most active. It is suspected that these include soy protein, bioactive peptides, interaction of isoflavones within the intact soy matrix or other compounds (Cassidy & Hooper 2006, Torres et al 2006). It is reported that isolated soy protein that maintains the native protein structure is more effective in reducing serum lipids than denatured protein (Hoie et al 2007). Soy protein is also reported to have beneficial effects on renal function, with suggestions that the isoflavones genistein and daidzein reduce glomerular damage by protecting LDL from oxidation and the high arginine content acts as a precursor for NO thus improving renal flow (Torres et al 2006).

Although it has been suggested that there is no evidence of beneficial effects of phyto-oestrogens on blood pressure, arterial compliance or oxidation of LDL cholesterol, there may be beneficial effects on endothelial function and homocysteine concentrations (Cassidy & Hooper 2006). This is supported by a study that reports that a greater isoflavone intake is associated with better vascular endothelial function and lower carotid atherosclerotic burden in people at high risk of cardiovascular events (Chan et al 2007). Soy supplementation has also been reported to improve endothelial function in renal transplant patients (Cupisti et al 2007). Soy isoflavones have, however, been found to improve systemic arterial compliance in perimenopausal and menopausal women (Nestel et al 1997). Soy protein, regardless of isoflavone content, modulates serum lipid ratios in a direction beneficial for cardiovascular disease risk in healthy young men (McVeigh et al 2006) and soy consumption is associated with decreased carotid intima-media thickness and plasma lipids with the association being stronger for men than women (Zhang et al 2008).

Anti-osteoporotic

There has been speculation that the oestrogenic effects of soy isoflavone may help prevent osteoporosis (Setchell & Cassidy 1999). A recent review of in vitro and in vivo studies suggests that soy protein prevents bone loss and that soy isoflavones stimulate the synthesis and the expression of alkaline phosphatases in osteoblasts, and food enriched with isoflavones prevented the reduction of bone mineral density (BMD) in ovariectomised rats or mice and inhibited excretion of urinary deoxypyridinoline (Horiuchi 2005). Animal studies have also found a synergy between soy isoflavones and supplemental calcium in improving BMD, particularly in the lumbar spine (Ward 2005).

In human trials, 35 g/day soy protein for 12 weeks was found to significantly reduce urinary deoxypyridinoline and increase total alkaline phosphatase in a small study of 15 women aged 45–64 years (Roudsari et al 2005); however, randomised trials in humans indicate that soy protein and soy isoflavones do not significantly affect calcium metabolism in postmenopausal women (Spence et al 2005)

or improve BMD (Horiuchi 2005), despite having an effect on markers of bone formation (Arjmandi et al 2005).

It has further been suggested that the beneficial effects of soy isoflavones on bone may be life-stage specific and dependent on the number of oestrogen receptors and the endogenous hormone milieu. Perimenopausal and early menopausal women may therefore be more receptive to the therapeutic effects of isoflavones on bone loss prior to the diminution of oestrogen receptors that occurs in the postmenopausal years (Reinwald & Weaver 2006).

Anticancer

To date there have been no positive human intervention studies and the evidence of soy's anticancer effects is based on epidemiological data, as well as in vitro and animal studies.

Soy phyto-oestrogens are converted by gut bacteria to derivatives with weak oestrogenic and antioxidative activities, and epidemiological studies suggest that the highest plasma levels of their metabolites are found in individuals living in countries or regions with low incidence of both cancer and cardiovascular disease (Mazur et al 1998). Although soy phyto-oestrogens have been implicated in soy's anticarcinogenic activity, a causal relation to disease prevention is hypothetical, as the exact mechanisms have not been elucidated (Adlercreutz 2002a, 2002b).

There are multiple mechanisms by which soy protein may protect against cancer, as there is evidence for soy isoflavones having oestrogenic, antioestrogenic, antioxidant, antiproliferative and antiangiogenic activities (Barnes et al 2000). Soy also contains other putative anticarcinogenic compounds such as lignans, saponins, phytates, protease inhibitors and phytosterols (Greenwood et al 2000) and it is possible that soy consumption may be a marker for other dietary factors.

It has been suggested that soy isoflavones may reduce breast cancer risk by affecting endogenous sex hormone concentrations and the menstrual cycle (Adlercreutz 2002a, 2002b, Setchell & Cassidy 1999) and that soy phyto-oestrogens may influence cancer growth through effects on oestrogen receptors, as well as through inhibition of tyrosine and other protein kinases, and other enzymes such as aromatase, alteration of growth factor activity and inhibition of angiogenesis (Adlercreutz 2002a, 2002b).

Genistein is the most studied of the phyto-oestrogens and has weak oestrogenic activity. It has also been found to cause apoptosis in cancer cells both in vitro and in vivo (Bylund et al 2000), stimulate several antioxidative enzymes, such as catalase, superoxide dismutase, glutathione peroxidase and reductase, induce tumour cell differentiation, downregulate the epidermal growth factor receptor and erbB2/Neu receptors in cancer cells, and also possibly inhibit tumour cell invasion by inhibiting MMP9 (92 kDa type IV collagenase) (Adlercreutz 2002a, 2002b). Genistein is also reported to inhibit angiogenesis, DNA topoisomerase II, protein tyrosine kinases, aromatase, NF-kappa-B and to downregulate TGF-beta and stimulate the sex hormone-binding globulin (PDRHealth 2004). Isoflavones have also been shown to inhibit the activity of aromatase (CYP19), thus decreasing oestrogen biosynthesis and producing antioestrogenic effects, which may be important in breast and prostate cancers (Moon et al 2006).

Soy isoflavones also demonstrate a variety of oestrogen-independent activities, and some of them are directly associated with the suppression of the invasive behaviour of breast cancer cells (Sliva 2005). Furthermore, it is suggested that variability in xenobiotic metabolising enzymes and the effect of flavonoid ingestion on enzyme activity may contribute to individual variations in susceptibility to diseases such as cancer (Moon et al 2006).

Although in vitro and animal models point to several pathways by which isoflavones may reduce incidence of cancer (Rosenberg Zand et al 2002), and experimental evidence also exists for an inhibitory effect of soy bran on prostate cancer growth and of isolated lignans on colon cancer (Adlercreutz 2002a, 2002b), clinical trial data supporting this are still lacking.

OTHER ACTIONS

Antioxidant

Oxygen stress is believed to contribute to menopause and degenerative changes associated with ageing and it is suggested that antioxidants, such as soy isoflavones, may help to protect mitochondria against premature oxidative damage (Miquel et al 2006). Although several clinical trials have suggested that soy intake decreases oxidative stress and that soy isoflavones, such as genistein, have antioxidant properties in vitro, results of supplementation in clinical trials are inconclusive. Furthermore, diets relatively high in soy protein or soy-derived isoflavones are reported to have little effect on plasma antioxidant capacity or biomarkers of oxidative stress (Vega-Lopez et al 2005). It has been suggested that genistein may be a potential therapy for multiple sclerosis as it has been observed to reduce experimental autoimmune encephalomyelitis in mouse models (De Paula et al 2008).

Cognitive function

Soy isoflavones may mimic the actions and functions of oestrogen on the brain, and they have been shown to have positive effects on the cognitive function in females, whereas results in males are inconsistent. Soy isoflavones, and particularly genistein, have been suggested to influence cognitive function via an oestrogen receptor-mediated pathway and via the inhibition of tyrosine kinase; however, definitive data are still lacking (Lee et al 2005).

CLINICAL USE

Soybeans are usually consumed as fermented and non-fermented soy foods such as tofu, miso and tempeh, as well as whole soybeans, soy nuts, soy milk or soy cheese, and soy flour is a common ingredient in foods, beverages and condiments (Sliva 2005). Wide variability has been reported in the total amount of isoflavones in commercial soy

products with levels being generally lower than the values on the product labels (Nurmi et al 2002).

Menopausal symptoms

The natural oestrogen receptor activity of soy is popularly considered an alternative to controversial hormone replacement therapy (HRT) for postmenopausal women (Sliva 2005). The results of numerous reviews and meta-analyses remain inconclusive. A recent Cochrane review of various phytooestrogens for vasomotor menopausal symptoms found a strong placebo effect in most trials and concluded there is no evidence of effectiveness in the alleviation of menopausal symptoms with the use of phytoestrogen treatments (Lethaby et al 2007). This is contrasted by a more specific review of 21 trials of soy and/or isoflavones on hot flushes and night sweats that suggests that, although results are inconsistent, most RCTs of isoflavone supplements found reductions in weekly hot flushes of between 7% and 40%; however, the quality of studies was generally low (Balk et al 2005). Another systematic review and meta-analysis that included 17 trials found that isoflavone supplementation significantly reduced flushes, with the percentage reduction being related to the number of baseline flushes per day and the dose of isoflavone studied (Howes et al 2006). A review that examined six systematic reviews and performed a meta-analyses of 25 randomised controlled trials (RCTs) assessing the use of phytoestrogens for the treatment of the climacteric syndrome found contradictory results with no statistically significant reduction of vasomotor symptoms for phyto-oestrogens (Tempfer et al 2007). Similarly a recent analysis of 17 trials found mixed results for the effects of soy isoflavone extracts on menopausal symptoms (Nelson et al 2006).

Theories explaining inconsistent results

Although some trial data seem to support the efficacy of isoflavones in reducing the incidence and severity of hot flushes, many studies have not found any difference between the isoflavone recipients and the controls (Greenwood et al 2000). These inconsistent results may be due to variations in the isoflavone content of the preparations used. A critical review of published studies stratified 11 studies according to genistein content and found the five studies that provided more than 15 mg of genistein all reported a statistically significant improvements in hot flushes while only one of the 6 studies that provided less than 15 mg of genistein reported any improvement (Williamson-Hughes et al 2006). In addition, confusion may arise from the fact that a variety of isoflavone sources have been tested, often without discriminating between the identities of individual isoflavones. The source of the isoflavones is not always stated which could be another important omission as bioavailability of active components could vary depending on the food matrix they are being presented in. As such, volunteers may be receiving greatly different doses or ranges of specific isoflavones from the different test products but researchers have not taken this into account when evaluating and comparing results. Finally, the composition and dose of soy supplements varies widely across studies, which makes comparisons and interpretations difficult (Low Dog 2005).

Cardiovascular disease

Substantial data from epidemiological surveys and nutritional interventions in humans and animals indicate that soy protein reduces serum total and LDL cholesterol and triglycerides, as well as hepatic cholesterol and triglycerides (Torres et al 2006). Based on this data, the US FDA has approved a food label health claim stating that a diet with a daily intake of 25 g of soy protein and low in saturated fat and cholesterol may reduce the risk of heart disease (Balk et al 2005). This claim, however, is only based on studies demonstrating beneficial effects on lipids and other biomarkers of risk, as there have been no published trials on the effects of soy on mortality or cardiovascular events (Cassidy & Hooper 2006). Furthermore, a review by the Nutrition Committee of the American Heart Association suggests that any reduction of serum lipids by soy protein is relatively small and that other benefits are not proven. As such soy supplementation is not recommended, despite acknowledgement that many soy products should be beneficial to cardiovascular and overall health because of their high content of polyunsaturated fats, fibre, vitamins, and minerals and low content of saturated fat (Sacks et al 2006).

Hypercholesterolaemia

At least six systematic reviews have assessed the effects of soy isoflavones on lipid levels, and suggest that a diet supplemented with soy protein isolate containing isoflavones reduces LDL cholesterol by approximately 0.15 mmol/L, but without clear effects on triglycerides or HDL cholesterol (Cassidy & Hooper 2006). In one of the systematic reviews that included a total of 68 RCTs, it is suggested that soy has small to moderate effects on lipids with significant reductions in total cholesterol (by 2.5%), LDL (3%), triglycerides (6%) and no significant change on HDL, and that the effect is independent of isoflavone content. This review further suggests that higher doses of soy protein are associated with greater LDL reduction in those with elevated baseline LDL levels (Balk et al 2005). A recent meta-analysis of 41 randomised controlled trials on isolated soy protein supplementation and serum lipids found similar results for total cholesterol, LDL and triglycerides but found that soy protein supplementation also resulted in a significant increase in HDL, with meta-regression analyses showing a dose–response relationship (Reynolds et al 2006). Similar results were reported in another meta-analysis of 23 RCTs published from 1995 to 2002. This study found that soy protein with isoflavones was associated with significant decreases in total cholesterol (by 3.8%), LDL (by 5.25%), and triglycerides (by 7.27%) and significant increases in serum HDL cholesterol (by 3.03%), with the observed changes being greater for those having higher baseline cholesterol levels or taking more than >80 mg/day isoflavone and the greatest lowering effects on total cholesterol and

LDL cholesterol occurred within short time frames, whereas improvements in HDL cholesterol were only observed in studies of longer than 12 weeks duration (Zhan & Ho 2005). A more recent meta-analysis on the effects of soy isoflavones without soy protein found that ingestion of 70 mg/day for 1–3 months does not improve total and LDL cholesterol levels in normocholesterolaemic menopausal women (Taku et al 2008).

Although many studies have reported that soy improves serum lipid levels, a critical analysis of investigations to date suggests that the effects are not impressive and questions the clinical importance of observed hypocholesterolaemic effects (Dewell et al 2006). More recent studies present inconsistent results. For example, one RCT found that a soy-based low-calorie diet significantly decreased serum total cholesterol and low-density lipoprotein cholesterol concentrations and had a greater effect on reducing body fat percentage than traditional low-calorie diets (Liao et al 2007) while another RCT suggests that regular consumption of foods providing 24 g soy protein/day from isoflavones had no significant effect on plasma LDL cholesterol in mildly hypercholesterolaemic subjects (Thorp et al 2008).

Blood pressure

In addition to beneficial effects on lipids, epidemiological data suggest that soy may affect blood pressure but this is not supported by clinical trial data. In an observational study of 45,694 participants of the Shanghai Women's Health Study, aged 40–70 years with no history of hypertension, diabetes or cardiovascular disease, the intake of soy foods over 2–3 years was inversely associated with both SBP and DBP, particularly among elderly women. Results of this study found that compared to women consuming less than 2.5 g/day of soy, consumption of more than 25 g/day was associated with a significant reduction in SBP of 1.9 mmHg and a significant reduction in DBP of 0.9 mmHg and that the inverse association between soy consumption and blood pressure became stronger with increasing age, with significant reductions of −4.9 mmHg for SBP and −2.2 mmHg for DBP in women aged over 60 years (Yang et al 2005).

Despite this epidemiological study, a recent systematic review evaluating all observation studies and clinical trials and subsequent meta-analysis found no reduction in blood pressure between patients treated with phyto-oestrogens and those on placebo (Rosero Arenas et al 2008). This is supported by a further review of 22 RCTs on the effect of soy consumption on blood pressure that found no discernible effect on either SBP or DBP (Balk et al 2005). The results of a recent RCT of low sodium soy sauce, however, suggests that the addition of soybean peptides to soy sauce results in a significant reduction in blood pressure in people with mild hypertension (Uchida et al 2008).

Cancer prevention

High levels of phyto-oestrogens (lignans and isoflavonoids) are frequently associated in epidemiological studies with low risk of breast, prostate and colon cancers, and breast cancer has been found to be associated with low lignan levels in the USA, Finland, Sweden and Australia.

In general, epidemiological studies have investigated the association between isoflavones and breast cancer risk by measuring dietary isoflavone intake, or levels of these in plasma/serum or urine, while some studies have looked at soy and breast cancer risk measuring exposure to soy-containing foods such as tofu and miso soup (Velentzis et al 2008). Two separate meta-analyses were conducted by Wu et al, which investigated the association in Western women and Asian women, accounting for the differences in dietary isoflavone intake (Wu et al 2008a). The results indicate that protective benefits are dose dependent. A meta-analysis of eight studies involving Asian women found that those consuming the highest amount (>20 mg/day) of dietary isoflavones had a 29% reduction in breast cancer risk when compared to low-level isoflavone intake (<5 mg/day). A moderate dose of 10 mg/day of isoflavones resulted in a 12% decrease in risk. In contrast, a meta-analysis of 11 studies carried out in women with Western diets found they consumed extremely low levels of isoflavones (median of highest intake was 0.8 mg/day and of lowest intake was 0.15 mg/day) and no association between isoflavone intake and breast cancer risk.

A meta-analysis of 21 studies found a significantly reduced incidence of breast cancer among past phyto-oestrogen users, while a review of 22 case-control and cohort studies that examined the incidence of breast cancer among women with and without a diet high in phyto-oestrogens found that none of the available RCTs document a protective effect of phytoestrogens for the clinical end points of breast cancer (Tempfer et al 2007). A meta-analysis of 18 epidemiological studies published from 1978 to 2004 that examined soy exposure and breast cancer risk concluded that high soy intake was modestly associated with reduced breast cancer risk with the association being stronger for premenopausal women (Trock et al 2006). This is supported by another review of the role of phyto-oestrogens, such as soy-containing isoflavones, for the prevention of breast cancer which concluded that a soy-containing diet in adult women is not or only slightly protective with regard to breast cancer, but may be beneficial if consumed in early life before puberty or during adolescence (Adlercreutz 2002a, 2002b).

Yet another meta-analysis of epidemiologic studies associating cancer risk with soy intake found statistically significant reductions in the mean overall risk estimate for breast (0.78), colon (0.70) and prostate (0.66) cancers for soy consumers (Badger et al 2005). This is supported by a study of over 35,000 Singapore Chinese women that found that 10 mg of isoflavones per day obtained in a standard serving of tofu had lasting benefits for the prevention of breast cancer in postmenopausal women (Wu et al 2008b). A further study suggests that the protective effect of soy differs by receptor status with reduced risk being evident in women who are oestrogen and progesterone receptor positive and HER2 receptor negative (Suzuki et al 2008). While

in vitro and rodent data have raised concerns that isoflavones may stimulate the growth of existing oestrogen-sensitive breast tumours, recent review suggests that there is little clinical evidence to suggest that isoflavones will increase breast cancer risk in healthy women or worsen the prognosis of breast cancer patients (Messina & Wood 2008).

A study of over 8300 Japanese men and women found no association between soy consumption and colon cancer (Akhter et al 2008).

Soy proteins, common in the Asian diet, have been shown to inhibit prostate cancer cell growth (Kurahashi et al 2008, Sonn et al 2005). In an epidemiological study of over 82,000 men legume intake was associated with a moderate reduction in prostate cancer risk that was deemed not to be due to isoflavones (Park et al 2008) while a case-controlled study suggests that isoflavones might be an effective dietary protective factor against prostate cancer in Japanese men (Nagata et al 2007). In RCTs in men aged 50–80 years, 12 months' supplementation with 83 mg/day isoflavones did not alter serum levels of prostate-specific antigen (PSA) in healthy men (Adams et al 2004), while 60 mg/day of soy isoflavone did alter serum PSA and free testosterone in some men with early stage prostate cancer (Kumar et al 2004). In another RCT involving 29 men with prostate cancer and scheduled to undergo a radical prostatectomy, supplementation with bread containing 50 g of soy grits was found to significantly reduce PSA levels (Dalais et al 2004).

Breast cancer survival

The role of soy isoflavone intake and the risk of breast cancer recurrence were investigated by Guha et al (2009). A cohort of 1954 Asian female breast cancer survivors was prospectively followed for 6.31 years and their dietary isoflavone intake was assessed on average 23 months postdiagnosis, using specific food frequency questionnaires (Guha et al 2009). Suggestive trends for a reduced risk of cancer recurrence were observed with increasing quintiles of daidzein and glycetin intake compared to no intake among postmenopausal women (*P* for trend: $P = 0.08$ for daidzein, $P = 0.06$ for glycetin) and among tamoxifen users ($P = 0.10$ for daidzein, $P = 0.05$ for glycetin). Among postmenopausal women treated with tamoxifen, there was an approximately 60% reduction in breast cancer recurrence comparing the highest to the lowest daidzein intakes (>1453 vs <7.7 microgram/day; HR, 0.48; 95% CI, 0.21–0.79, $P = 0.008$). Based on these findings, soy isoflavones consumed at levels comparable to those in Asian populations may reduce the risk of cancer recurrence in women receiving tamoxifen therapy and, importantly, does not appear to interfere with tamoxifen efficacy. Furthermore, it suggests that there is no evidence to indicate that soy foods are unsafe in breast cancer patients.

Two studies have explored prediagnosis phyto-oestrogen intake and breast cancer survival. One was conducted in the US and considered dietary intake of isoflavones in 1210 newly diagnosed pre- and postmenopausal breast cancer patients (Fink et al 2007). The highest quintile for consumption experienced a 48% lower risk of all-cause mortality compared with the lowest quintile of isoflavone intake. A similar reduction in risk was found for breast cancer mortality but it was limited to postmenopausal women.

In contrast, no association was found in Asian population according to a second study (Boyapati et al 2005). Dietary information gathered during a 5-year period prior to diagnosis was collected from 1459 Chinese breast cancer patients (both pre- and postmenopausal) finding no overall association between soy intake (either as total soy protein or as total isoflavone) prior to cancer diagnosis and disease-free breast cancer survival in the highest tertile of intake compared with those in the lowest tertile.

Clinical note — Soy and breast cancer patients

Whether soy and concentrated isoflavone sources confer beneficial or harmful effects in people with breast cancer has remained a controversial topic for some years.

The NSW Cancer Council supports the consumption of soy foods in the diet as part of the national dietary guidelines to eat a diet high in plant-based foods. A position statement released in 2006 states that the Cancer Council does **not** recommend or support the use of supplements such as soy protein isolates or isoflavone capsules for healthy men and women to prevent cancer and does not recommend or support the use of supplements for breast cancer survivors. There is evidence to suggest that women with existing breast cancer or past breast cancer should be cautious in consuming large quantities of soy foods or phyto-oestrogen supplements (Cancer Council 2009). Recent evidence indicates no harmful effects of including soy isoflavones consumed at levels comparable to those in Asian populations, and possibly benefits. In vivo studies suggest that the isoflavone daidzein may enhance the effect of tamoxifen against breast cancer burden and incidence. Whilst further research is required to confirm these findings, it appears that soy and isoflavone intake may not be as harmful as once thought.

Osteoporosis prevention

Isoflavone intervention has been found to significantly inhibit bone resorption and stimulates bone formation. A recent meta-analysis of 10 studies suggests that isoflavone intervention significantly attenuates bone loss of the spine in menopausal women (Ma et al 2008). Clinical data further suggest that effects become more significant when more than 90 mg/day of isoflavones are consumed (Ma et al 2008) while limited epidemiologic data among Asian populations generally suggests that lower amounts are efficacious (Messina et al 2004). The relationship between usual soy food consumption and fracture incidence was studied in 24,403 postmenopausal women aged 40–70 years who had no history of fracture or cancer in the Shanghai Women's Health Study. During a mean follow-up of 4.5 years, a statistically significant association

was found between soy or isoflavone consumption and fracture risk, with the association being more pronounced among women in early menopause (Zhang et al 2005).

A systematic review found 31 studies that evaluated the effect of soy on markers of bone health; however, few of these were long-term studies and they involved a wide variety of interventions making overall conclusions difficult. Of the five studies longer than 1 year, no consistent effect was seen on BMD or markers of bone formation (Balk et al 2005). Another systematic review that evaluated 15 clinical trials looking at the effects of isoflavones or isoflavone-rich soy protein on BMD suggests that isoflavones reduce bone loss in younger postmenopausal women (Messina et al 2004). A recent RCT has suggested that 24 months of treatment with genistein has positive effects on BMD in osteopenic postmenopausal women (Marini et al 2007) while another trial suggests that soy protein-containing isoflavones showed a modest benefit in preserving spine, but not hip BMD in older women (Newton et al 2006).

Cognitive function

A recent review of eight studies published in 2000–2007 found inconsistent outcomes with four of the seven studies conducted in postmenopausal women revealing a positive impact of isoflavones on cognitive function. The authors suggest that multiple factors such as variation in the composition of phytoestrogen interventions and the heterogeneous characteristics of the study population could have contributed to the discrepant results (Zhao & Brinton 2007).

OTHER USES

Soy infant formula

Soy has been used as an alternative for cow's milk in infant feeding for more than 30 years and may account for as much as 25% of infant formula (Mendez et al 2002). Soy formula is commonly used for infants with cow's milk allergy and there is evidence to suggest that soy milk may be effective in reducing infant colic (Garrison & Christakis 2000). There are few studies, however, examining the effects of phyto-oestrogens in infants. Although infants consuming soy formula may be exposed to 6–11 mg/kg/day of phyto-oestrogens and have plasma levels of isoflavones an order of magnitude higher than adults consuming soy foods (Setchell & Cassidy 1999), there is no obvious evidence to suggest any negative effects (Mendez et al 2002, Setchell & Cassidy 1999).

Diabetes and diabetic nephropathy

Replacing animal protein with soy protein has been found to improve various disease markers in patients with type 1 or type 2 diabetes and people with obesity. In a RCT of 104 patients with type 2 diabetes, 12 months of a soy-based meal replacement was found to significantly improve weight loss, HbA_{1c} and high-sensitivity C-reactive protein levels and significantly reduce the use of sulfonylureas and metformin compared to the use of individual diet plans (Li et al 2005). Another randomised trial involving 90 obese (non-diabetic) subjects suggests that 6 months on a low-fat, high-soy-protein diet can help to reduce fat while preserving muscle mass and improving glycaemic control and the lipid profile (Deibert et al 2004).

Soy protein supplementation is also reported to be of benefit in a number of pilot studies of diabetic nephropathy. In a controlled crossover trial, 8 weeks of substituting soy protein for animal protein significantly reduced glomerular filtration rates in 12 young adults with type 1 diabetes mellitus (Stephenson et al 2005). In another crossover trial, isolated soy protein significantly reduced urinary albumin and improved lipid profiles in 14 men with type 2 diabetes and nephropathy (Teixeira et al 2004). Similarly, improvement in lipid profile and renal function was observed in another randomised, crossover clinical trial of 14 patients with type 2 diabetes and nephropathy consuming a 35% soy protein and 30% vegetable protein diet for 7 weeks (Azadbakht et al 2003).

Seasonal allergic rhinitis

Polysaccharides from soy sauce have been shown to have anti-allergic activities in vitro and in vivo, and an 8-week double-blind study involving 51 subjects with seasonal allergic rhinitis found that oral supplementation with 600 mg of soy polysaccharides was effective in significantly improving symptom scores such as sneezing, nasal stuffiness and hindrance of daily life, as well as significantly improving the appearance and state of the nasal mucosa (Kobayashi 2005, Kobayashi et al 2005).

Premenstrual syndrome (PMS)

Isolated soy protein containing 68 mg/day (aglycone equivalents) soy isoflavones was found to significantly improve specific PMS symptoms, including headache, breast tenderness, cramps and swelling in a seven-menstrual cycle, double-blind, placebo-controlled, crossover intervention study in 23 women (Bryant et al 2005).

DOSAGE RANGE

Soy foods contain variable amounts of isoflavones. Soy flour contains 1.3 mg/g of isoflavones, with tofu containing 0.4 mg/g, soy milk 0.25 mg/g, tempeh 0.4 mg/g, miso 0.92 mg/g, soy sauce 0.023 mg/g, soybean paste 0.57 mg/g and soy cheese 0.05 mg/g (Coward et al 1993). Soy isoflavones are also available in some functional food products. Although soy oils and lecithin are used in many food ingredients, the typical Western diet provides negligible isoflavones, whereas Asian diets typically contain 20–50 mg of isoflavones (Nagata et al 1998). The optimal dose required to have clinical effects is yet to be established; however, the benefits seen in epidemiological studies are achieved with approximately 50 mg/day of isoflavones (Setchell & Cassidy 1999) and it is suggested that optimal soy protein and isoflavone intakes are 15–20 g/day and 50–90 mg/day, respectively with 25 g/day recommended for cholesterol reduction (Messina 2008).

TOXICITY

Soy and soy isoflavones are considered non-toxic in the doses that are generally consumed as foods. Soy may interfere with the absorption of synthetic thyroid hormone, and there is a theoretical concern based on in vitro and animal data that soy foods may increase risk of developing clinical hypothyroidism in individuals with compromised thyroid function and/or whose iodine intake is marginal (Messina & Redmond 2006). Soy food consumers should ensure their intake of iodine is adequate although studies suggest that soy isoflavones in a protein matrix do not significantly influence circulating thyroid hormones in healthy young men (Dillingham et al 2007).

Although the phyto-oestrogens may have hormonal activity, they have relatively short half-lives of approximately 6–8 h, which is contrasted with the environmental xeno-oestrogens that may persist for years in fat tissue and hence bio-accumulate (Setchell & Cassidy 1999).

ADVERSE REACTIONS

There is little suggestion of adverse effects of soy or isoflavones at physiological doses, although soy isoflavone supplements have induced gastrointestinal discomfort and menstrual complaints (Cassidy & Hooper 2006). Unconjugated soy isoflavones appear to be safe and well tolerated in healthy postmenopausal women at doses of 900 mg/day (Pop et al 2008).

Women with breast cancer (especially oestrogen-positive tumours) and men with prostate cancer should avoid the use of soy isoflavone supplements pending long-term safety studies. There is a case report of a 60-year-old man having gynaecomastia and breast tenderness along with high oestradiol levels due to soy milk consumption (Martinez & Lewi 2008).

There are structural similarities between birch pollen and soy allergens leading to allergic cross-reactions (Kleine-Tebbe et al 2008) and the potential for anaphylaxis (Jacquenet et al 2008).

SIGNIFICANT INTERACTIONS

Antibiotic administration blocks metabolism of isoflavones to equol through inhibition of the intestinal microflora, whereas a high carbohydrate milieu increases intestinal fermentation and results in more extensive biotransformation of phyto-oestrogens (Setchell & Cassidy 1999).

It has been suggested that isoflavones can inhibit the oxidative and conjugative metabolism of drugs in vitro and interact with transporters such as P-glycoprotein; however, their ability to interact with drugs remains uncertain until clinical studies can confirm these findings (Evans 2000).

Calcium, magnesium, zinc, copper and iron

Soy contains phytic acid, which may bind with certain minerals, such as calcium, magnesium, manganese, zinc, copper and iron, reducing their availability (PDRHealth 2004). Separate by 2–3 hours.

PRACTICE POINTS/PATIENT COUNSELLING

- Soy is a component of many foods and a nutritious source of protein.
- There are many different types and formulations of soy and people may react differently to soy products depending on their diet and the activity of their gut bacteria.
- In countries where people regularly consume soy products there appears to be lower incidence of cardiovascular disease, menopausal symptoms and some cancers.
- The most active agents in soy are the isoflavones, which are used to treat menopausal symptoms, and prevent osteoporosis, cancer and heart disease; however, their use is not yet based on large-scale clinical trials.
- The ability of soy to reduce menopausal symptoms is uncertain at present.
- Although there has not been much research on the use of soy in infants, there does not appear to be any adverse effects of feeding infants with soy formula.
- The long-term benefits of soy may relate to the lifetime exposure to the use of soy products.

Tamoxifen

Whilst the soy isoflavone genistein may theoretically compete with tamoxifen for oestrogen receptors, thereby reducing drug efficacy, a large prospective study found that soy isoflavones consumed at levels comparable to those in Asian populations may reduce the risk of cancer recurrence in women receiving tamoxifen therapy and, importantly, does not appear to interfere with tamoxifen efficacy. Furthermore, it suggests there is no evidence to indicate that soy foods are unsafe in breast cancer patients (Guha et al 2009).

Additionally, in vivo studies suggest that the isoflavone daidzein may enhance the effect of tamoxifen against breast cancer burden and incidence — possible beneficial effect under professional supervision. Usual dietary intake levels appear safe; however, the safety of concentrated extracts is yet to be established.

PREGNANCY USE

Soy is likely to be safe when used as a food; however, pregnant women and nursing mothers should avoid the use of soy isoflavone supplements pending long-term safety studies.

PATIENTS' FAQs

What will this supplement do for me?

Soy is a nutritious food and a good source of protein that appears to have beneficial effects on cholesterol, and possible activity against cancer, heart disease, osteoporosis and may positively affect cognitive function.

When will it start to work?

Clinical studies suggest the effects of soy take between 6 and 12 weeks to appear.

Are there any safety issues?

Soy is generally considered safe when taken as a food source or protein substitute; however, soy isoflavone supplements should be taken with caution in pregnancy, and in those with breast cancer or prostate cancer.

Stinging nettle

HISTORICAL NOTE Stinging nettle has been used since ancient times, with Dioscorides and Galen in ancient Greece reporting diuretic and laxative effects for nettle leaf. It is also widely used for gynaecological complaints by North American Indians and in Ayurvedic medicine in India (Blumenthal et al 2000). The Latin root of *urtica* is *uro*, meaning 'I burn', indicative of the small stings caused by the hairs on the leaves of nettle when contact is made with the skin.

OTHER NAMES

Common nettle, brenessel, brennesselkraut, brennesselwurzel, urtica ortie, great stinging nettle, haarnesselkraut, haarnesselwurzel.

BOTANICAL NAME/FAMILY

Urtica dioica (family Urticaceae)

PLANT PARTS USED

Aerial parts and root.

CHEMICAL COMPONENTS

Constituents found within the leaf include vitamins A and C, beta-carotene, calcium and potassium, phosphorus, chlorophyll, magnesium and tannins, flavonoids, sterols and amines (US Department of Agriculture 2003).

Constituents found chiefly in the root include polysaccharides, lectins, lignans, fatty acids, terpenes and coumarin (Ernst et al 2001).

MAIN ACTIONS

Anti-inflammatory and analgesic

In vitro studies have identified anti-inflammatory activity for *Urtica* extract (Obertreis et al 1996a, 1996b, Riehemann et al 1999). The mechanism of action has not been fully elucidated, but test tube studies have demonstrated inhibitory effects on NF-kappa B activation and partial inhibitory effects on cyclo-oxygenase and 5-lipoxygenase derived reactions. Additionally, isolated phenolic acid from nettle has been shown to inhibit leukotriene B4 synthesis in a concentration-dependent manner in vitro.

Although extensive investigation has not been conducted in humans to confirm anti-inflammatory mechanisms, one study of 20 volunteers showed that oral ingestion of 1.34 g nettle extract for 3 weeks significantly decreased lipopolysaccharide-stimulated tumor necrosis factor-alpha (TNF-alpha) and interleukin-1 beta (IL-1-beta) when tested ex vivo but had no effects on cytokine levels (Teucher et al 1996).

In vitro data have shown that nettle leaf extract (IDS 30) reduces the induction of primary T-cell responses and TNF-alpha in T-cell mediated diseases such as rheumatoid arthritis (Broer & Behnke 2002). Faecal IL-1-beta and TNF-alpha concentrations were significantly reduced in mice with induced Crohn's disease treated with IDS 30 (Konrad et al 2005). Mice treated with nettle extract displayed less histological changes and general disease symptoms. The authors conclude that the effect may be due to a decrease in TH1 response and may constitute a new treatment option for prolonging remission in inflammatory bowel disease.

Hypotensive and diuretic

When administered intravenously to test animals, *Urtica* extract exerts an acute hypotensive action accompanied by diuretic and natriuretic effects (Tahri et al 2000). It is uncertain whether the same effects are seen with oral administration.

A review of in vitro and in vivo studies concluded that the hypotensive action of *U. dioica* is due in part to negative inotropic activity and a vasodilatory effect (Testai et al 2002).

Antihyperglycaemic

A 33% reduction in blood glucose was noted in rats administered 250 mg/kg of nettle leaf extract orally, 30 min before glucose loading (Bnouham et al 2003). Nettle was shown to decrease glucose absorption in the small intestine of rats under anaesthesia; however, administration of 500 mg/kg failed to modify blood glucose levels in alloxan-induced diabetic rats.

A sixfold increase in blood insulin levels occurred after intravenous administration of a nettle leaf fraction in streptozotocin-diabetic rats, with a corresponding drop in blood sugar levels as compared to control (Farzami et al 2003). Details of the isolated fraction were not given.

Antiproliferative effects on prostate cells

Nettle extract has shown antiproliferative effects on prostate cells; however, the exact mechanism of action has not been fully elucidated (Lichius & Muth 1997, Lichius et al 1999). Results from several in vitro studies suggest that a combination of mechanisms is responsible. It seems likely that sex hormone binding globulin (SHBG), aromatase, epidermal growth factor and prostate steroid membrane receptors are involved in the antiprostatic effect, but less likely that 5-alpha reductase or androgen receptors are involved (Chrubasik et al 2007)

Prostate cancer

One study found that a methanolic extract of stinging nettle roots slows the progression of prostate cancer in both an in vivo model and an in vitro system (Konrad et al 2000). One study involving 20 males with prostatic adenoma found that treatment for 7 days with nettle produced a significant drop in zinc level, thought to be a result of altering zinc-testosterone metabolism and diminishing zinc secretion in adenomatous tissue (Romics & Bach 1991).

Antiviral

A lectin extracted from nettle had inhibitory effects against HIV-1, HIV-2, human cytomegalovirus, respiratory syncytial virus and influenza A virus in vitro (Balzarini et al 1992).

Antioxidant

Nettle has shown potent antioxidant activity in a range of in vitro tests (Gulcin et al 2004): 50, 100 and 250 microgram inhibited peroxidation of linoleic acid by 39%, 66% and 98%, respectively, as compared to 30% inhibition demonstrated by 60 microgram/mL of alpha-tocopherol.

In the same study, nettle was shown to scavenge free radicals, hydrogen peroxide and superoxide anion radicals and to chelate heavy metals. Ozen and Korkmaz (2003) reported that constituents from nettle can regulate glutathione reductase, glutathione peroxidase, superoxide dismutase and catalase in vivo.

The fixed oil of nettle has demonstrated strong antioxidant activity in mice treated with carbon tetrachloride, by decreasing lipid peroxidation and increasing antioxidant status (Kanter et al 2003). Nettle extract is significantly effective in preventing fibrosis in liver tissue from carbon tetrachloride damage in vivo (Turkdogan et al 2003). Dried nettle added to the diet of rats decreased cerebral free radicals after forced-swim tests (Toldy et al 2005).

Hepatoprotective

Treatment with stinging nettle effectively protected against aflatoxin-induced hepatotoxicity, as evidenced by decreased aspartate aminotransferase (AST), alanine aminotransferase (ALT) and gamma glutamyl transpeptidase (GGT) levels, and hepatic lipid peroxidation and elevated the antioxidants' levels in an animal model (Yener et al 2009). These findings were confirmed by histological observation. One mechanism proposed to account for this observation is nettle-maintained antioxidant enzyme activity (superoxide dismutase, catalase and glutathione reductase) which protected against hepatotoxic effects induced by aflatoxin. Comparisons between groups revealed the untreated animals experienced a significant decrease in antioxidant enzyme activity, whereas no significant changes were seen with co-administration of nettle treatment.

CLINICAL USE

Different parts of the nettle herb have been used for different indications. Some evidence comes from traditional usage; however, most recent research efforts have investigated various nettle preparations in urological and rheumatological conditions.

Arthritic conditions

Traditionally, nettle herb and leaf have been used to treat painful joint diseases, but scientific investigation has only just begun to determine whether there is a demonstrable benefit with its use.

One randomised, double-blind crossover study involving 27 patients with osteoarthritic pain at the base of the thumb or index finger compared topical applications of stinging nettle leaf with placebo, used daily for 1 week. After a 5-week washout period, treatments were then reversed. Nettle application used for 1 week showed reduction in pain and disability and produced significantly superior results to placebo (Randall et al 2000). An open study of 17 patients reporting beneficial effects with the nettle sting of *U. dioica* showed that a transient urticarial rash can be associated with topical use (Randall et al 1999). It is suspected that a counterirritant effect is chiefly responsible.

In a multicentre study of 152 subjects with degenerative rheumatic conditions, 1.54 g dried nettle herb extract produced a subjective improvement in 70% of cases after 3 weeks.

Most recently, a randomised, controlled, single-blind pilot study investigated the feasibility of conducting research to determine the effect of the sting of *Urtica dioica*, for chronic knee pain. Patients were instructed to apply a specific number of nettle (*Urtica dioica*) leaves to the affected area, or

placebo intervention with *Urtica galeopsifolia* daily for 1 week. The effect of *U. dioica* did not appear to be superior to the control treatment; however, the authors suggested several possible interpretations of this negative result. Importantly, during the study it was found that the choice of placebo was poor as *Urtica galeopsifolia* had a stinging irritant effect similar to stinging nettle. Next, there was the possibility of inadequate treatment as researchers found it difficult to supply well-grown nettles in late season, and not all patients used as many leaves as recommended. Finally, the study may have been underpowered to detect a statistical difference between groups.

Clearly, further clinical research is required to clarify the effectiveness of *Urtica dioica* in musculoskeletal conditions.

Commission E approved stinging nettle as supportive therapy for rheumatic ailments when used internally or applied externally (Blumenthal et al 2000).

Benign prostatic hyperplasia (BPH)

Clinical trials have used many different nettle extracts in liquid or oral dose forms. The Bazoton products (Kanoldt) have been most commonly investigated; however, there has also been some investigation with extracts including Urtica plus (Osterholz/Schwarzpharma), Urtica APS (Zyma/Novartis), Prostatin (Abbott), Prostaherb (Cesra), and Prosta Truw (Truw).

According to a 2007 systematic review, at least 40,000 men with BPH have been treated with various nettle root preparations in 34 clinical studies (Chrubasik et al 2007). Twenty-four studies were open and uncontrolled, two studies were open and controlled and six were randomised controlled studies. All studies evaluated methanolic nettle root extracts. Overall, available evidence indicates that methanolic nettle extracts are effective in BPH. Most studies report decreased residual urine volume, increased maximal urinary flow and improvements in symptom scores compared to placebo. Significant improvements in prostate size have also been reported in some open trials (ESCOP 1996–97). Further randomised studies are required to determine the significance and magnitude of these effects. Commission E approved the use of *Urtica* root for difficulty in urination in BPH stages 1 and 2 (Blumenthal et al 2000).

In combination

In practice, nettle root preparations are often prescribed in combination with other herbal medicines, such as saw palmetto or pygeum. Several clinical trials have investigated combination products which are more reflective of practice, overall producing positive results.

Nettle and pygeum

In one study, 134 patients with BPH were randomly assigned an *Urtica* and *Pygeum* preparation (300 mg *Urtica dioica* root extract combined with 25 mg *Pygeum africanum* bark extract) or a preparation containing half that dose under double-blind test conditions for 8 weeks. Both treatments significantly increased urine flow, and reduced residual urine and nocturia after 28 days, whereas after 56 days further significant decreases were found in residual urine (half-dose group) and in nocturia (both groups) (Krzeski et al 1993).

Nettle and saw palmetto extract

In 1995, an open, prospective, multicentre observational study involving 419 specialist urological practices investigated the efficacy and tolerability of a saw palmetto and nettle combination in 2080 patients with BPH (Schneider et al 1995). Herbal treatment was seen to improve pathological findings and obstructive and irritative symptoms. Both efficacy and tolerability were assessed by physicians as very good or good and most patients reported an improvement in general quality of life (QOL) and reduction in symptoms of BPH.

A randomised, multicentre double-blind study involving 543 patients with early stage BPH found that a combination of nettle and saw palmetto extract was as effective as finasteride at increasing maximum urinary flow and improving International Prostate Symptom Scores (IPSS) after 24 weeks' treatment, which continued to improve by week 48 (Sokeland 2000). Improvement in QOL scores was similarly observed with both treatments, regardless of prostate size. Overall, the two treatments only differed in regard to adverse reaction incidence, with the herbal combination much better tolerated (Sokeland & Albrecht 1997). A 2003 review concluded that a combination of nettle and saw palmetto is safe and effective for the treatment of lower urinary tract symptoms associated with BPH, comparable to the alpha-blocker tamsulosin (Bondarenko et al 2003).

A randomised, placebo-controlled, double-blind, multicentre trial in 2005 further demonstrated the effectiveness of saw palmetto fruit (160 mg) and nettle root (120 mg) for lower urinary tract symptoms due to prostate enlargement (Lopatkin et al 2005): 257 men aged 50 years or more were randomised to take either two capsules of the study medication (320 mg saw palmetto and 240 mg nettle root) daily or placebo for 24 weeks. Men on the treatment experienced a 35% reduction in symptoms — most notably intermittency, hesitancy, urgency and nocturia — compared to 24% for placebo. At the end of the 24-week period, an open trial was conducted for an additional 24 weeks and all men were given the herbal medicine. Those previously taking placebo reported significant improvements when switched to the study medication.

Allergic rhinitis

A double-blind randomised study showed that a freeze-dried preparation of nettles improved global assessments of allergic rhinitis after 1 week's therapy (Mittman 1990).

OTHER USES

Diarrhoea, dysentery and diseases of the colon, internal bleeding, chronic skin eruptions such as eczema, discharges and arthritic conditions.

DOSAGE RANGE

Leaf
- dry extract: 0.6–2.1 g/day in divided doses; or
- liquid extract (1:2): 15–40 mL/week.

Root
- Although Commission E recommend 4–6 g/day cut root for symptoms of BPH, doses up to 18 g/day have been used (www.phytotherapies.org June 2003).

TOXICITY
Insufficient reliable evidence is available.

ADVERSE REACTIONS
One report states that gastrointestinal discomfort, allergic reactions, urticaria, pruritus, oedema and decreased urine volume are possible (Ernst et al 2001).

Clinical studies in BPH with herbal combinations containing nettle have found that only 0.72–3.7% experience mild adverse effects.

Urticaria due to stinging nettle
A frequent cause of contact urticaria is skin exposure to the stinging nettle. The urticaria is accompanied by a stinging sensation lasting longer than 1/2 h. Part of the immediate reaction to nettle stings is due to histamine introduced by the nettle (Oliver et al 1991). It has also been found that both hair and plant extracts of nettle contain high levels of leukotriene B4 and C4, besides histamine, which add to the irritant effects (Czarnetzki et al 1990).

SIGNIFICANT INTERACTIONS
Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

Diuretic medicines
Potentiated effects are theoretically possible — observe patients taking this combination.

Antihypertensive medicines
Additive effects are theoretically possible — observe patients taking antihypertensives concurrently.

Finasteride
Additive effects are theoretically possible, although the interaction may be beneficial.

CONTRAINDICATIONS AND PRECAUTIONS
People with known sensitivities or allergies to stinging nettle should use this herb cautiously.

PREGNANCY USE
Use of nettle during pregnancy is contraindicated because of its effects on hormones (WHO 2003).

PATIENTS' FAQs
What will this herb do for me?

Nettle leaf may reduce pain in osteoarthritis when applied topically for 1 week, whereas oral preparations of nettle root in combination with saw palmetto or pygeum reduce symptoms of BPH. Internal preparations may also reduce symptoms of allergic rhinitis, according to one human study.

When will it start to work?

Topical applications of the leaf in osteoarthritis have been shown to work after 1 week, whereas benefits in BPH require at least 28 days' treatment.

Are there any safety issues to be concerned about?

Local application of nettle can be irritating and cause contact urticaria, but preparations taken internally seem generally well tolerated.

PRACTICE POINTS/PATIENT COUNSELLING
- Preliminary research has demonstrated anti-inflammatory, analgesic and antiviral activities for nettle.
- Several test tube studies have shown that it reduces prostate cell proliferation and slows the progression of prostate cancer in both an in vivo model and an in vitro system.
- The aerial parts are most commonly used to relieve symptoms of arthritis, whereas the root is used for BPH symptom relief.
  - There is good evidence that stinging nettle extracts provide significant symptom relief in BPH and some studies indicate a possible reduction in prostate size.
- Application of nettle leaf for 1 week reduced pain and disability in arthritis under double-blind test conditions.
- One double-blind study found that nettle reduced symptoms of allergic rhinitis.
- Studies using nettle root in combination with saw palmetto or pygeum have shown positive results in BPH.

Taurine

BACKGROUND AND RELEVANT PHARMACOKINETICS

Taurine occurs as one of the most abundant free amino acids in a wide variety of animal tissues; it is mostly absent from plants (Bouckenooghe et al 2006). In man and other mammals, the highest taurine concentrations are found in heart, retina, spleen and bone marrow (Timbrell et al 1995). Blood cells such as platelets and leucocytes are also very rich in taurine.

Traditionally taurine has been regarded as an end product of methionine metabolism. Other pathways for taurine biosynthesis exist but they have not been fully characterised and in mammals the cysteinsulfinate pathway seems to be the major pathway (Brosnan & Brosnan 2006).

There is marked variation in taurine biosynthesis in different organs and it is species- and age-dependent. The activity of cysteine sulfinic acid decarboxylase, a key enzyme in the biosynthesis of taurine from cysteine (Lambert 2004), is low in the liver and brain of human fetuses, infants and adults. The extent to which taurine can be synthesised by man is unknown at present.

Taurine does not undergo any major metabolic biotransformation, although a small amount is deaminated to isethionic acid. As taurine is metabolically inert, free taurine is readily excreted in the urine. The kidney is the major organ involved in regulating taurine levels (Chesney et al 1985, Rozen & Scriver 1982) and excess dietary taurine is excreted in the urine (Sturman 1988).

A small amount of taurine is also degraded by intestinal bacteria to sulfate, which is absorbed from the intestine and excreted in urine. The high tissue taurine levels in both mature and newborn animals

have led to much speculation about possible roles of taurine in brain, retina, heart and skeletal muscle (Grimble 2006).

CHEMICAL COMPONENTS

2-Aminoethanesulfonic acid

FOOD SOURCES

Taurine does not need to be supplied in the diet of man as it can be derived indirectly from dietary precursors. Dietary taurine is found preformed in considerable quantities in meat, fish and seafood (Roe & Weston 1965). Daily intake of preformed taurine can be 40–400 mg/day (Hayes & Trautwein 1994, Rana & Sanders 1986).

DEFICIENCY SIGNS AND SYMPTOMS

Since the 1970s there have been several reports documenting degeneration of the retina in taurine-deficient cats. Studies indicated that cats have a limited ability to synthesise taurine, and develop low plasma and tissue concentrations when fed taurine-free diets (Knopf et al 1978). The animals showed growth retardation and developed retina degeneration that eventually led to blindness. The retina degeneration could be prevented or reversed by the addition of preformed taurine to the diets, but not by feeding methionine or cysteine.

Deficiency

Taurine deficiency manifests as neuronal dysfunction. This has been demonstrated in a study of children receiving parenteral nutrition without supplemental taurine that developed low taurine plasma levels and neuronal (especially retinal) dysfunction, which could be counteracted by taurine supplementation (Geggel et al 1985).

Taurine deficiency has been reported in parenteral nutrition as taurine is not routinely added to the parenteral formulations (Lloyd & Gabe 2007).

Taurine deficiency can present in infants with cholestatic disease and this can be prevented by parenteral supplementary taurine; extensive gastrointestinal surgery can also result in taurine deficiency due to increased loss of bile acids (Lloyd & Gabe 2007, Schneider et al 2006).

MAIN ACTIONS

Many studies report that taurine is involved in a wide variety of biological processes although the exact mechanisms of action are usually not well defined.

Taurine has been proposed to have numerous roles such as a membrane stabiliser, a neurotransmitter/neuromodulator, an intracellular osmolyte and an antioxidant and may have a number of other roles including immunomodulation and growth modulator (Bouckenooghe et al 2006, Huxtable 1992, 1996). The evidence that taurine is indispensable in human nutrition remains unclear although dietary taurine has been shown to play an important part in maintaining body taurine pools.

Bile acid conjugation

Despite extensive studies on the proposed functions of taurine, the only well-defined role for taurine is conjugation with bile acids. Taurine is preferentially conjugated with bile acids in the liver, forming predominantly taurocholic acid, prior to excretion in the bile (Bouckenooghe et al 2006). Bile acids have an important role in the emulsification of dietary fat.

OTHER ACTIONS

Animal studies indicate that taurine supplementation may result in lower plasma lipid levels (Murakami et al 2002) and improve insulin sensitivity (Anuradha & Balakrishnan 1999, Nakaya et al 2000).

The compound taurine chloramine (Tau-Cl) is reported to act as an antioxidant; it is produced when hypochlorous acid produced in the 'oxidant burst' of stimulated neutrophils and monocytes, interacts with taurine (Grimble 2006). Studies report that Tau-Cl down-regulates the production of pro-inflammatory mediators and to also have antibacterial properties (Schuller-Levis & Park 2004).

Cell membrane stabilisation

Taurine reportedly acts as a modulator of membrane excitability in the central nervous system by inhibiting the release of other neurotransmitters and decreasing mitochondrial release of calcium (Grimble 2006, Muramatsu et al 1978).

Osmoregulation

It has been suggested that taurine plays an important role in osmoregulation due to its biophysical and biochemical properties (Huxtable 1992); however, this characteristic may be significant in some species and not in others.

Calcium modulation

Taurine is a modulator of intra- and extracellular calcium levels and is able to both increase Ca^{2+} availability and resist against Ca^{2+} overload, depending on the circumstances (Bradford & Allen 1996).

Xenobiotic conjugation

Taurine can conjugate with xenobiotics and animal studies indicate that this is to a varying degree, being dependent on the animal species (Nakashima et al 1982).

CLINICAL USE

Deficiency: treatment and prevention

Taurine deficiency has not been significantly investigated in man, so the information is generally derived from in vitro and animal studies. Taurine deficiency may be reflected by low plasma levels and these can be normalised by supplementary taurine.

Growth and development

Findings from animal studies have shown that maternal diet supplemented with taurine during late gestation resulted in higher fetal plasma taurine

levels and the offspring had increased postnatal growth, although the mechanism for this has not been elucidated (Hultman et al 2007).

Adult humans have a low activity of hepatic cysteine sulfinic acid decarboxylase and infants, especially premature infants, possess even lower enzyme activity. It has therefore been suggested that infants and particularly premature infants may have a greater requirement for preformed taurine than adults (Sturman et al 1975).

A systemic review by Verner et al (2009) assessed the effect of supplemental taurine versus no supplementation on the growth and development of preterm or low birth weight infants who were fed via enteral and parenteral nutrition. The authors identified nine small studies in which supplemental taurine was given with formula milk via enteral feeding in eight studies and supplemental taurine via parenteral nutrition in one study. Meta-analyses of these randomised or quasi-randomised controlled trials showed that supplemental taurine did not result in improved outcomes. However, the infants in these studies were clinically stable and the majority were greater than 30 weeks gestational age at birth and it may be that taurine requirements are different among infants who are ill or in other sub-groups.

Cardiovascular disease (CVD)

Various studies have indicated reduced CVD risk from supplementary taurine intake alone or in combination with $n-3$ polyunsaturated fatty acids (PUFA) (Militante & Lombardini 2004, Mizushima et al 1997). Studies by Yamori et al (2001, 2006) found urinary taurine excretion as the most significant single factor to correlate inversely with ischaemic heart disease (IHD) mortality and they also highlighted the benefits of combined taurine and $n-3$ fatty acids with respect to IHD mortality.

Elvevoll et al (2008) studied hypolipidaemic and anti-atherogenic effects of taurine and $n-3$ fatty acids in 75 healthy adults in a 7-week double-blind and parallel intervention trial where one group received $n-3$ PUFA, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) (1.1 g EPA + DHA/day) and the second group received both $n-3$ and taurine (425 mg/day). The results of this study demonstrated the beneficial effect of $n-3$ combined with taurine producing significant reductions in total cholesterol, low-density lipoprotein (LDL) cholesterol and apolipoprotein (apo) B in the $n-3$ + taurine group compared to the $n-3$ group alone.

Hypertension

In a randomised, controlled study of 31 borderline hypertensive adults and normal adults, 6 g taurine was given daily for 7 days; although the normal subjects did not experience any effects, the intervention group experienced a significant decrease in blood pressure and serum catecholamines (Fujita et al 1987).

In another randomised, controlled study of 11 healthy adult males taking 6 g taurine/day in presence of a high fat, high cholesterol diet for 3 weeks, there was no change in blood pressure but there was a significant increase in very low-density lipoproteins (VLDLs) and triglycerides (Mizushima et al 1996).

Obesity

In a small randomised, controlled study, 15 healthy overweight adults were treated with 3 g taurine/day for 7 weeks resulting in significant decrease in serum triglycerides although there was no change in high-density lipoprotein (HDL) cholesterol or fasting glucose (Zhang et al 2004a). In a somewhat larger study of 30 overweight or obese non-diabetic young subjects, taurine supplementation (3 g/day; 1 g × 3 times/day) over a 7-week period resulted in a beneficial effect on lipid metabolism and a decrease in body weight (Zhang et al 2004b).

Diabetes

In contrast to findings from animal studies, human studies do not altogether support a role for taurine in the management of diabetes; a study of 22 patients with type 2 diabetes who were treated with 3 g taurine/day for 4 months found no effect on glycated haemoglobin A1c (HbA_{1c}) or fasting glucose (Chauncey et al 2003). Likewise, a double-blinded, randomised, crossover study of 20 non-diabetic subjects who were overweight first-degree relatives of type 2 diabetes mellitus (T2DM) patients received a daily supplementation of 1.5 g taurine or placebo; the results of this study showed that taurine supplement did not exert any effect on blood lipid levels or insulin secretion or sensitivity in subjects with both genetic and some non-genetic factors predisposing them to T2DM (Brøns et al 2004). Similarly, Spohr et al (2005) showed that taurine supplementation had no effect on platelet aggregation in 20 healthy men with a predisposition to T2DM. A study by Franconi et al (1995) looking at 1.5 g/day of taurine supplementation for 90 days in 39 patients with insulin-dependent diabetes mellitus (IDDM), with healthy, age and sex-matched subjects, found that taurine reduced platelet aggregation in patients with diabetes whereas aggregation was not affected in the controls.

Epilepsy

Several studies have investigated the role of taurine supplementation in the management of seizure disorders, overall producing inconsistent results. In some studies, patients with severe intractable epilepsy were administered taurine either orally or intravenously, varying in both duration and dose (from 200 mg/day and up to 21 g/day), making comparisons difficult. Additionally, most studies were uncontrolled and flawed with regard to methodology thereby hindering accurate interpretation (Fariello et al 1985). Some studies reported a reduction in seizure frequency (Takahashi & Nakane 1978), whereas others did not observe any benefit (Mantovani & DeVivo 1979).

The optimal dose of taurine supplementation in the management of epilepsy may be in the range of 100–500 mg/day with a recent study by Gaby (2007) noting loss of anti-seizure activity in some patients when the dose was increased to above 1.5 g/day. According to this study, beneficial effects

are relatively short lasting and are not maintained beyond a few weeks of treatment. Additional studies are required to clarify the role of taurine supplementation in practice.

DOSAGE RANGE

Taurine is administered orally usually in divided doses; adult dosage is generally 500 mg to 3 g daily and paediatric dosage 250 mg to 1 g daily and these are dependent on the size and age of the child.

There appear to be very few health concerns regarding taurine supplementation, although safety has been of interest recently because of the high intakes that can be easily consumed from some sports drinks (Munro & Renwick 2006).

TOXICITY

In a risk assessment by Shao & Hathcock (2008) the following recommendations have been made: no observed adverse effect level (NOAEL) and lowest observed adverse effect level (LOAEL) > 10 g taurine/day; observed safe level (OSL) 3 g/day; upper level for supplements (ULS): 3 g/day.

ADVERSE REACTIONS

Taurine administration appears to be safe, even at higher doses. Children should be monitored for any adverse side effects and supplementation ceased if any adverse effects develop.

At dosages of 2 g/day, patients with psoriasis experienced intense, temporary itching (Kendler 1989); dosages of 1.5 g taurine/day caused nausea, headache, dizziness and gait disturbances in some epileptic patients (Van Gelder et al 1975).

SIGNIFICANT INTERACTIONS

Controlled studies are not available and at present there are no known drug interactions with taurine.

CONTRAINDICATIONS AND PRECAUTIONS

High doses of taurine (10 g/day for 6 months) have been taken without any major side effects (Durelli et al 1983); the longest duration recorded has been 1 year (Colombo et al 1988). Many commercially available energy drinks contain substantial amounts of supplementary taurine (1000 mg/L) and as there is very little information about the effects of these doses, the young, people who are immunocompromised, pregnant and nursing mothers should consult a relevant health professional before excessive intake. People with psoriasis and epilepsy should avoid high intakes of taurine.

PREGNANCY USE

At present there is no evidence to prove the benefit of taking supplementary taurine during pregnancy.

PATIENTS' FAQs

What will this supplement do for me?

Decreased plasma levels can be normalised by taurine supplementation. There is some evidence that taurine may be a useful treatment in CVD.

When will it start to work?

Plasma taurine levels can increase within a week of taking supplementary taurine.

PRACTICE POINTS/PATIENT COUNSELLING

- Taurine can be readily obtained by eating meat, fish and seafood.
- Most people are able to produce taurine naturally; however, young infants are limited in their ability to produce taurine and obtain their dietary taurine from either breast milk or supplemented milk formulas
- Plasma taurine levels can be low in some illnesses and conditions (such as sepsis) and can be restored with supplementary taurine.
- At present there is no evidence to prove the benefit of taking taurine during breastfeeding.
- Traditionally taurine has been used in CVD, hypertension and hyperlipidaemia.
- 'Energy' soft drinks may contain taurine as well as caffeine although the potential interactions between these two ingredients have not been determined.

Are there any safety issues?

Generally taurine supplementation has a good safety profile.

Tea tree oil

HISTORICAL NOTE The Bundjalong Australian Aboriginal people of northern New South Wales knew of the medicinal qualities of this plant's leaves for many centuries and used it to treat burns, cuts and insect bites. It was not until the 1700s that it became known in the Western world as 'tea tree' because Captain Cook found its aromatic leaves an enjoyable substitute for real tea. The first official report of its medicinal use appeared in the *Medical Journal of Australia*, in 1930, when a Sydney surgeon wrote of its impressive wound healing and antiseptic qualities (Murray 1995). In modern times, tea tree oil has become widely accepted as a standard treatment for wounds and minor skin infections.

COMMON NAME
Tea tree

OTHER NAMES
Australian tea tree oil, melaleuca, melasol, narrow-leaved paperbark, paperbark tree oil, punk tree, ti tree oil

BOTANICAL NAME/FAMILY
Melaleuca alternifolia (family Myrtaceae)

PLANT PARTS USED
Essential oil from leaves and branches

CHEMICAL COMPONENTS
Tea tree oil contains many active constituents, including cineole, alpha-cadinine, terpinenes, pinenes, alpha-terpineol, aromadendrene, terpinenols and terpinolene (Duke 2003). Purified components have been found to have greater antibacterial and fungicidal activities than the whole oil,

with terpinen-4-ol being the most active (Loughlin et al 2008, Terzi et al 2007).

Antifungal and antibacterial

The in vitro evidence of antifungal and antibacterial activities is overwhelming. In vitro results find that tea tree oil has activity against a range of yeasts and fungi found in common mucosal and skin infections, such as *Corynebacterium* spp., *Klebsiella pneumoniae*, *Micrococcus* spp. (*M. luteus*, *M. varians*), *Propionibacterium acnes*, *Streptococcus pyogenes*, *Trichomonas vaginalis*, *Pseudomonas aeruginosa*, *A. baumannii*, *Staphylococcus* spp. (*S. aureus*, *S. capitis*, *S. epidermidis*, *S. haemolyticus*, *S. hominis*, *S. marcescens*, *S. saprophyticus*, *S. warneri* and *S. xylosus*) and *Candida* spp. (Bagg et al 2006, Carson et al 2006, Concha et al 1998, De Mondello et al 2003, Hada et al 2001, Hammer et al 1996, 1998, Messager et al 2005, Murray 1995, Papadopoulos et al 2006, Tortorano et al 2008). Importantly, tea tree oil has been shown to have activity against methicillin-resistant *Staphylococcus aureus* (MRSA) and coagulase-negative *Staphylococci* (CoNS) (Brady et al 2006, Loughlin et al 2008).

It is suggested that the antibacterial activity of tea tree is due to its ability to effectively bind to the bacterial cell wall (Chung et al 2007). Tea tree oil disrupts the permeability barrier of cell membrane structures of microorganisms and denatures the proteins (Carson et al 2002, Cox et al 2000, Gustafson et al 1998, Tao et al 2006). This activity is similar to disinfectants such as chlorhexidine and quaternary ammonium compounds.

Antiviral

An in vitro study has identified activity against herpes simplex virus (HSV) types 1 and 2 (Schnitzler et al 2001).

Oestrogenic and antiandrogenic activities

Studies in human cell lines have indicated that tea tree oil has oestrogenic and antiandrogenic activities and it is suggested that this may have contributed to treat the cases of prepubertal gynaecomastia, with topical use (Henley et al 2007).

Other actions

Tea tree oil is reported to have anti-inflammatory activity (Carson et al 2006) and animal studies have demonstrated that inhalation of tea tree oil has both anti-inflammatory and immunomodulatory actions that are likely to be mediated by the hypothalamic pituitary axis (Golab & Skwarlo-Sonta 2007).

CLINICAL USE

Topical tea tree oil preparations have been investigated in a number of clinical studies, either as the oil itself or as an ingredient of gels, creams or ointments. In vitro studies suggest that the penetration of topical tea tree oil components through the skin is limited (Cross et al 2008).

Acne vulgaris

A randomised, double-blind, placebo-controlled study of 60 patients found that a topical 5% tea tree oil gel was an effective treatment of mild-to-moderate acne vulgaris (Enshaieh et al 2007). This result is supported by a single-blind, randomised clinical trial involving 124 patients with mild-to-moderate acne and showed that a similar gel significantly improved the condition and reduced the number of acne lesions. These effects were similar to 5% benzoyl peroxide lotion, but tea tree oil gel was better tolerated and produced fewer side effects (Bassett et al 1990).

Tinea pedis

Under double-blind, randomised test conditions, 104 subjects with tinea pedis (athlete's foot) used 10% w/w tea tree oil cream or 1% tolnaftate or placebo creams as treatment (Tong et al 1992). In this study, significantly more tolnaftate-treated patients (85%) than tea tree oil- (30%) and placebo-treated (21%) patients showed conversion to negative culture at the end of therapy. However, tea tree oil cream reduced symptoms as effectively as tolnaftate 1%. A more recent randomised, double-blinded, controlled study by the same group used a higher concentration of tea tree oil (25% and 50%) for the treatment of interdigital tinea pedis in 158 patients over 4 weeks (Satchell et al 2002a). In the 50% tea tree oil group, 68% of patients had a significant response and 64% achieved negative mycology. In the 25% tea tree group, 72% of patients responded and 50% were cured. The placebo responder rates were 39% and 31%, respectively, with 3% of patients using tea tree developing dermatitis. It is suggested that the fungicidal activity of tea tree and other essential oils can be enhanced using footbaths heated to 42°C (Inouye et al 2007).

Toenail infection (onychomycosis)

A randomised, double-blind multicentre study involving 177 volunteers found that 6 months' treatment with 1% clotrimazole solution (applied twice daily) or 100% tea tree oil (applied twice daily) produced similar results, improving nail appearance and associated symptoms (Buck et al 1994). Additionally, 3 months after either treatment ceased, continued improvement or complete resolution was observed in approximately half of participants. One randomised, double-blind, placebo-controlled study investigated the effects of a combined tea tree oil (5%) and butenafine hydrochloride (2%) cream in chronic toenail onychomycosis and found that after 6 weeks, 80% of patients achieved a cure compared with none using placebo cream (Syed et al 1999).

MRSA infection

Washing with 5% tea tree oil (TTO) has been shown to be effective in removing MRSA on the skin (Thompson et al 2008) and tea tree oil has been effectively used against biofilm formation on tympanostomy tubes in vitro (Park et al 2007). A combination of 4% tea tree oil nasal ointment and 5% tea tree oil body wash was found to be superior to the standard 2% mupirocin nasal ointment and triclosan body wash used for the eradication of MRSA (Caelli et al 2000).

A recent review concluded that tea tree oil was not statistically superior to the standard treatment mupirocin for MRSA (Flaxman & Griffiths 2005). The paper reported on two RCTs (n = 30, n = 224), both of which demonstrated that tea tree oil was as effective as mupirocin. In the larger trial, 224 patients were given either mupirocin 2% nasal ointment, chlorhexidine gluconate 4% soap and silver sulfadiazine 1% cream or tea tree 10% cream and tea tree 5% body wash for 5 days (Dryden et al 2004). Rates of MRSA clearance were similar: 41% in the tea tree group and 49% using standard treatment. Mupirocin was significantly more effective at clearing nasal carriage (78%) than tea tree cream (47%); however, tea tree treatment was more effective than both chlorhexidine and silver sulfadiazine at clearing superficial skin sites and skin lesions. Although encouraging, more large clinical trials are needed to examine the efficacy of tea tree in both treating and preventing MRSA infection (Thompson et al 2008).

Although tea tree oil may be an effective antimicrobial agent when appropriately used at bactericidal concentrations, its application at sublethal concentrations may contribute to the development of antibiotic resistance in human pathogens (McMahon et al 2007).

Vaginitis and cervicitis

Clinical data support the use of tea tree oil for vaginitis and cervicitis caused by *Trichomonas vaginalis* or *Candida albicans* (WHO 2003, Vila & Canigueral 2006). An open study found that intravaginal application of tampons saturated in a diluted emulsified solution successfully healed vaginitis and cervicitis (n = 130) caused by *T. vaginalis*. Vaginal pessaries containing 0.2 g essential oil inserted nightly eradicated symptoms of leucorrhoea and burning in 86% of women with *C. albicans* vaginitis after 30 days with 75% of women also becoming free of infection (WHO 2003).

A case report shows that a 5-day course of 200 mg tea tree oil in a vegetable oil base inserted into the vagina may also be successful at treating vaginal candidiasis with eradication of anaerobic bacterial vaginosis being confirmed after 1 month (Blackwell 1991).

Cystitis

A randomised, double-blind study investigated the effects of tea tree oil, administered as 8 mg essential oil (taken three times daily) in an enteric-coated capsule, in 26 women with chronic idiopathic colibacillary cystitis (Belaiche 1988). After the 6-month test period, 54% of women receiving active treatment were symptom free compared with only 15% receiving placebo. Although symptom free, 50% of women in the tea tree group still showed evidence of infection.

Gingivitis

Tea tree oil was as effective as chlorhexidine against *Streptococcus mutans*, the bacteria that causes gingivitis, in a controlled study of 30 individuals (Groppo et al 2002). A more recent double-blind, randomised, longitudinal study evaluated and compared the effects of tea tree oil gel (2.5%) and chlorhexidine gel (0.2%) in 49 patients with severe chronic gingivitis (Soukoulis & Hirsch 2004). Subjects brushed with the tea tree, chlorhexidine or placebo gel, twice daily, for a period of 8 weeks. Tea tree oil significantly reduced the papillary bleeding index and gingival index, but did not reduce plaque.

Dandruff

Tea tree oil is effective for the treatment of dandruff. A randomised, single-blind, parallel-group study investigated the efficacy of tea tree oil shampoo (5%) and placebo in 126 patients with mild-to-moderate dandruff over 4 weeks (Satchell et al 2002b). The tea tree oil group achieved a 41% improvement as compared to 11% in the placebo group, with no adverse effects.

OTHER USES

Cold sores

Since tea tree oil exhibits antiviral activity in vitro, tea tree oil preparations have been used in the treatment of herpes simplex. Clinical trials investigating tea tree oil for this indication are not available, so it is unknown whether effects are clinically significant.

Head lice eradication

In test tube studies, topical application of tea tree oil was extremely effective against head lice, with 93% of lice and 83% of eggs destroyed (Veal 1996). Phenols, phenolic ethers, ketones and oxides appear to be the major toxic components responsible for this activity. Using a mite chamber assay, tea tree oil was also found to be effective against both head lice and dust mites (Williamson et al 2007). While there is anecdotal evidence for its clinical use, this has not yet been confirmed by clinical trials (Centre 2008).

Hair follicle mite eradication (ocular demodecosis)

In a retrospective review of 11 cases, lid scrub with 50% tea tree oil combined with daily lid hygiene and tea tree shampoo for 4 weeks was observed to effectively eradicate the hair follicle mite *Demodex folliculorum* and result in subjective and objective improvements (Gao et al 2007).

Dermatitis

Tea tree oil may be an effective treatment for dermatitis in dogs. Tea tree oil cream (10%) was applied, twice daily, for 4 weeks to 53 dogs suffering from chronic dermatitis, allergic dermatitis, interdigital pyoderma, acral lick dermatitis and skinfold pyoderma (Fitzi et al 2002). At the end of the trial, 82% of the animals had a good or very good response to treatment with most symptoms disappearing, although two dogs experienced local irritation. Another trial by the same research team again evaluated the tea tree cream and blinded the study with a commercial skin care cream (Reichling et al 2004). Fifty-seven dogs were involved in this study and again the results were similar, with drastically reduced dermatitis in 71% of animals as compared to 41% using the control cream. A local reaction was reported in one dog.

Wart eradication

There is a report that daily topical application of tea tree oil for 12 days successfully eradicated warts on the hand of a paediatric patient (Millar & Moore 2008).

DOSAGE RANGE

Tea tree oil is used in a variety of forms, such as gels, creams, ointments, oral rinses, soaps, shampoos and paints. Minimum bactericidal concentrations are generally 0.25%.

- Onychomycosis: 100% essential oil applied twice daily.
- Tinea pedis: 10% essential oil in cream base applied twice daily.
- Acne: 5% essential oil in cream or gel base applied daily.
- Vaginitis (*Candida albicans* or *Trichomonas vaginalis*): intravaginally applied tampons saturated in a 1% emulsified solution, vaginal pessaries containing 0.2 g essential oil.
- Cervicitis (*Candida albicans* or *Trichomonas vaginalis*): intravaginally applied tampons saturated in a 20% emulsified solution.

TOXICITY

Tea tree oil should not be ingested. Accidental ingestion has resulted in confusion, disorientation, general malaise and coma, according to case reports (WHO 2003).

One case has been reported of an infant ingesting less than 10 mL of 100% oil, which resulted in confusion and an inability to walk within 30 min, followed by a full recovery within 5 h (Jacobs & Hornfeldt 1994).

ADVERSE REACTIONS

Anecdotal evidence from almost 80 years of use suggests that the topical use of the oil is relatively safe, and that adverse events are minor, self-limiting and occasional (Hammer et al 2006). Contact dermatitis is possible in sensitive individuals (Hammer et al 2006, Williams et al 2007) and it suggested that this is underreported and that tea tree oil should be included in patch testing. Oxidised monoterpenes are likely to be the sensitising agents (Reichling et al 2006) as tea tree oil from freshly opened products elicits no or weak reactions. It is therefore suggested that patch testing needs to be done with oxidised tea tree oil (Rutherford et al 2007).

Three cases of prepubertal gynaecomastia have been reported in boys who had used topical products containing lavender and tea tree oils with the gynaecomastia resolving after the products were discontinued (Henley et al 2007).

SIGNIFICANT INTERACTIONS

None known.

CONTRAINDICATIONS AND PRECAUTIONS

Caution should be exercised if applying the oil to eczematous or inflamed skin as it may cause irritation. It is suggested that a small amount be first applied to a test patch, to determine whether irritation will occur, as contact dermatitis has been reported.

PRACTICE POINTS/PATIENT COUNSELLING

- 100% tea tree oil is a safe and effective alternative to clotrimazole for the treatment of toenail onychomycosis.
- Extensive in vitro testing has found significant activity against a wide range of bacterial and fungal microorganisms, such as common skin pathogens.
- 5% tea tree oil gel has been shown to significantly improve acne vulgaris, with effects similar to 5% benzoyl peroxide lotion.
- Clinical evidence supports the use of tea tree oil preparations in *Candida albicans* or *Trichomonas vaginalis* vaginitis and cervicitis, cystitis and MRSA infection. It may also be useful in herpes simplex and head lice, but clinical data are unavailable.
- Tea tree oil should not be ingested other than in capsule form under professional supervision and a test patch is advised before widespread topical application.

PREGNANCY USE

Insufficient reliable information is available to determine safety.

PATIENTS' FAQs

What will tea tree oil do for me?

Tea tree oil is an antiseptic substance that is effective against a wide range of common bacterial and fungal organisms. Scientific evidence shows that it is an effective treatment for acne, fungal infections of the toenails, *Candida albicans* or *Trichomonas vaginalis* vaginitis and cervicitis, cystitis and MRSA infection. It is also used to treat cold sores and head lice.

When will it start to work?

This will depend on the indication it is being used to treat. In some cases, clinical tests are not available, so it is uncertain when, if any, effects are seen.

Are there any safety issues?

Tea tree oil should not be ingested orally and used with caution on inflamed and sensitive skin.

Thyme

HISTORICAL NOTE Although thyme has been used as a cooking spice for centuries in Europe, it is also used medicinally to treat common infections, coughs, bronchitis and asthma. The 17th century herbalist Nicholas Culpeper recommended thyme for whooping cough, gout, stomach pains and shortness of breath. It was also used in perfumes and embalming oils. In medieval times the plant was seen as imparting courage and vigour (Blumenthal et al 2000).

COMMON NAME
Thyme

OTHER NAMES
Common thyme, garden thyme, farigola, folia thymi, gartenthymian, herba thymi, almindelig timian, thym, thymian, thymianblätter, timo

BOTANICAL NAME/FAMILY
Thymus vulgaris (family Lamiaceae)

PLANT PARTS USED
Leaves and flowering tops

CHEMICAL COMPONENTS
The primary constituents are the volatile oils (1–2.5%), which include phenols (0.5%), namely thymol (30–70%), eugenol and carvacrol (3–15%), also flavonoids, apigenin, luteolin and saponins and tannins. Rosmarinic acid, caffeic acid and calcium are also found in significant quantities (Duke 2003). The herb also contains bitter principles and salicylates.

MAIN ACTIONS
Although thyme has not been significantly investigated in human studies, there has been some investigation into the activity of thymol and the volatile oil component of the herb. It is not known whether results obtained for these constituents are representative for the crude herb, but they provide some further understanding. Both the essential oil and thymol are ingredients in many proprietary products.

Antitussive and antispasmodic effects
These actions have been attributed to the phenolic compounds in thyme (WHO 2003). Antispasmodic effects on trachea and guinea pig ileum have been demonstrated for these constituents and for the whole extract of thyme (Engelbertz et al 2008).

Expectorant
The saponin content is believed to have expectorant activity, as demonstrated in animal studies. An in vivo trial has demonstrated improved expectoration and mucociliary clearance (Wienkotter et al 2007).

Antibacterial
In vitro tests have demonstrated activity of thyme extract against *Escherichia coli*, *Listeria monocytogenes*, *Streptococcus mutans* and *Salmonella enterica* (Burt et al 2005, 2007, Fabian et al 2006, Friedman et al 2002, Hammad et al 2007, Schelz et al 2006, Solomakos et al 2008). A review of the antibacterial and antifungal properties of the essential oil of thyme in vitro has demonstrated effectiveness against a wide range of pathogens including *Clostridium botulinum*, *E. coli*, *Haemophilus influenzae*, *Klebsiella pneumoniae*, *Salmonella typhi*, *Staphylococcus aureus* and *Candida albicans* (Kalemba & Kunicka 2003). Effects are most likely due to the eugenol, thymol and carvacrol constituents. Aqueous thyme extract also exhibited a significant inhibitory effect on *Helicobacter pylori*, reducing both its growth and its potent urease activity in vitro (Tabak et al 1996). More recently an extract of thyme was found to potentiate the anti-bacterial effects of tetracycline against methicillin-resistant *Staphylococcus aureus* in vitro (Fujita et al 2005). The compound baicalein was thought to be responsible.

Antifungal
Thymol and eugenol have demonstrated antifungal activity by establishing the ability to alter the cell wall and membrane of the yeasts *Saccharomyces cervisiae* and *Candida albicans* (Bennis et al 2004, Braga et al 2007b, Braga et al 2007a).

Antiviral
Thyme oil demonstrates antiviral activity against HSV-1, HSV-2 and an acyclovir-resistant strain of the virus (Koch et al 2007, Nolkemper et al 2006, Schnitzler et al 2007). One study found that the oil decreased plaque formation by more than 90% when preincubated with HSV-2, however no effect was observed when the oil was added prior to infection or after the absorption stage (Koch et al 2007). It was suggested that thyme essential oil interferes with the viral envelope.

Antioxidant
Three in vitro studies have investigated the antioxidant effects of thyme (Braga et al 2006a, Chizzola et al 2008, Lee et al 2005). One study found that eugenol, carvacrol, thymol and 4-allylphenol (5 μg/mL) all inhibited the oxidation of hexanal for a period of 30 days, demonstrating potent antioxidant activity comparable to alpha-tocopherol (Lee et al 2005). An in vivo study also found that thyme exerted significant antioxidant effects in a N-nitrosodiethylamine-induced oxidative stress model in rats (Rana & Soni 2008).

Astringent
The tannin content of the herb is chiefly responsible for its astringent activity.

Anthelmintic
Thymol possesses anthelmintic activity, demonstrated in vitro (Newell et al 1996).

Anti-inflammatory
Thymol has demonstrated anti-inflammatory effects in vitro by reducing elastase (Braga et al 2006b). A combination of oregano and thyme essential oils has been shown to reduce inflammation in trinitrobenzene sulfonic acid (TNBS)-induced colitis in vivo (Bukovska et al 2007). A dose of 0.2% thyme and 0.1% oregano led to a reduction in IL-1 beta, IL-6, GM-CSF and TNFalpha. The oils also decreased mortality rate, increased body weight and reduced histological damage.

OTHER ACTIONS
Thyme may possess antithrombotic properties (Naemura et al 2008).

CLINICAL USE
Thyme has not been significantly investigated in controlled studies, therefore information is generally derived from evidence of activity and traditional use, and the clinical significance is unknown.

Respiratory tract infections
Thyme extract has been used to treat the common cold, bronchitis, laryngitis and tonsillitis. It is orally ingested or used in a gargle for local activity, based on the herb's suspected antimicrobial and antitussive activities.

Bronchitis
Encouraging data have been reported for chronic bronchitis treated by thyme in combination with other herbs in large ($n > 3000$) comparative clinical trials, although no data are available for thyme as a stand-alone treatment (Ernst et al 1997). A combination of thyme and primrose root (1 mL five times/day) has been found to be beneficial in both double-blind and single-blind trials (Gruenwald et al 2005, 2006). The double-blind, placebo controlled, randomised, multicentre trial in 150 outpatients with acute bronchitis found that 58.7% of participants in the treatment group were symptom free at the end of the 7 to 9 days compared to 5.3% in the placebo group (Gruenwald et al 2005). A double-blind, placebo controlled, multicentre study investigated the efficacy of the same combination in 361 outpatients with acute bronchitis or severe cough (Kemmerich 2007). The combination successfully reduced coughing fits by 67.1% compared to 51.3% on days 7 to 9 ($P < 0.0001$). The active group reported a 50% reduction in coughing on average 2 days earlier than the placebo group. The singular effect of thyme in this formula however is uncertain.

A postmarketing surveillance study investigated the effects of a different mixture containing thyme and ivy as a syrup (Bronchipret Saft) in 1234 children and adolescents with acute bronchitis (Marzian 2007). Coughing fits reduced by 81.3% by day 10 and the responder rates for the various age groups were 92.0 to 96.5%. The singular effect of thyme in this formula however is uncertain.

Thyme is approved by Commission E in the treatment of bronchitis, whooping cough and upper respiratory tract catarrh (Blumenthal et al 2000).

Diarrhoea
The astringent activity of thyme provides a theoretical basis for its application in this condition.

Gastritis and dyspepsia
The bitter principles present in the herb and its antispasmodic activity provide a theoretical basis for its use in these conditions.

Skin disinfection (topical use)
Thyme extract has been used topically for infection control in minor wounds. The herb's antimicrobial and astringent activity provides a theoretical basis for this use.

OTHER USES
Traditionally, it has been used to aid in labour and delivery, promote menstruation and topically for warts and inflamed swellings (Fisher & Painter 1996). It has also been used to treat enuresis in children.

DOSAGE RANGE

Internal use
- Fluid extract (1:1): 1–2 mL up to three times a day.
- Fluid extract (1:2): 15–40 mL/week.
- Tincture (1:5): 2–6 mL three times daily.
- Infusion of dried herb: 1–4 g three times daily.

External use
- 5% infusion used as a compress.

ADVERSE REACTIONS
The volatile oil is considered an irritant topically and can cause nausea and vomiting, headache, dizziness, convulsions, cardiac or respiratory arrest if taken internally (Newell et al 1996). As such, the crude herb is considered far safer.

Contact dermatitis reactions have been reported with topical use (Lorenzi et al 1995).

SIGNIFICANT INTERACTIONS
Thyme may induce enzymes in phase one and two detoxification in the liver (Sasaki et al 2005). The clinical significance of this is unknown.

CONTRAINDICATIONS AND PRECAUTIONS
Contraindicated in people who are allergic to the Lamiaceae (Labiatae) family of plants. Other cautions are gastritis, enterocolitis and congestive heart failure (Ernst et al 2001).

PREGNANCY USE
Essential oil not recommended in pregnancy.

PATIENTS' FAQs
What will this herb do for me?
When taken internally, thyme is used to treat bronchitis, symptoms of the common cold, diarrhoea and dyspepsia. It is also used as an antiseptic gargle

for sore throats and can be diluted and applied externally to minor wounds.

When will it start to work?

The lack of human studies for this herb make it difficult to determine when effects will start to occur.

Are there any safety issues?

Thyme should not be used by people allergic to the Lamiaceae (Labiatae) family of plants or in pregnancy, and it should be used with caution in gastritis, enterocolitis and congestive heart failure.

PRACTICE POINTS/PATIENT COUNSELLING

- Although thyme is used as a cooking spice, it is also used medicinally to treat common upper respiratory tract infections, coughs, bronchitis and asthma, dyspepsia and diarrhoea.
- Thyme extract is used as a gargle for pharyngitis or applied topically (5% dilution) as a compress to wounds due to its antimicrobial and astringent activities.
- Thyme has not been significantly investigated in controlled trials, so much information is based on traditional use or evidence of activity.
- Thyme has antispasmodic, antimicrobial, antitussive, astringent and anthelmintic activities as demonstrated in vitro or in animal studies.

Tribulus

HISTORICAL NOTE Widely distributed in the Mediterranean region, Middle East and southern Africa, tribulus is an important plant used in traditional Ayurvedic, Arabic and Chinese medicine. Different parts of the tribulus plant are used to treat a variety of conditions, such as cough, colicky spasms, diarrhoea, haemorrhage, cardiovascular disease, rheumatic pain, gout, various kidney disorders, including kidney stones, and as an insect repellent.

COMMON NAME
Tribulus

OTHER NAMES
Al-gutub, cats-head, devil's-thorn, devil's-weed, goathead, puncture vine, qutiba

BOTANICAL NAME/FAMILY
Tribulus terrestris (family Zygophyllaceae)

PLANT PARTS USED
Leaf or fruit

CHEMICAL COMPONENTS
Different parts of the plant contain different constituents in varying ratios. Overall, the steroidal saponin content is considered the most important and includes constituents such as protodioscin, diosgenin, yamogenin, epismilagenin, tigogenin, neotigogenin, gitogenin and neogitogenin (Miles et al 1994). More steroidal saponins have been isolated from extracts of tribulus fruit in the past 5 years (Huang et al 2003, Su et al 2008, 2009, Xu et al 2008). The significance of this has not yet been determined. Beta-sitosterol, vitamin C, potassium and calcium are also found in the herb (Li et al 1998). Two major alkaloids have been identified: harmane and norharmane (Bourke et al 1992).

Of the steroidal saponins, protodioscin is considered the chief constituent responsible for the plant's effects on libido and sexual functioning. Preliminary observations suggest that *Tribulus terrestris* grown in different soils does not consistently produce this constituent and considerable variations have been identified in commercial products (Ganzera et al 2001). Steroidal saponins consist of a furostanol- or spirostanol-based aglycone and an oligosaccharide attached to a steroid nucleus. Steroidal saponins are very common in the plant kingdom and are natural components in many foods, such as asparagus, garlic and oats.

MAIN ACTIONS
Tribulus has not undergone significant clinical investigation; therefore, evidence of activity primarily derives from animal and in vitro studies. Additionally, some studies have investigated the pharmacological effects of the isolated saponin content.

Increases libido and enhances sexual function
Administration of tribulus extracts to animals improves libido and spermatogenesis. The exact mechanism by which tribulus influences sexual behaviour is not known, but increasing androgenic status and nitric oxide (NO) release appear to be chiefly responsible (Gauthaman et al 2002). More specifically, some reports have suggested that increases in dehydroepiandrosterone (DHEA) and testosterone are possible (Adimoelja 2000, Gauthaman et al 2002).

The constituent protodioscin is considered the most important in this regard and is converted to DHEA. Additionally, ex vivo tests have observed pro-erectile effects with protodioscin due to increased release of NO from the endothelium and nitronergic nerve endings (Adaikan et al 2000). Hormonal effects of tribulus were tested in primates, rabbits and rats. Administration of tribulus demonstrated a statistically significant increase in testosterone and DHEA levels in the primates, an increase of these hormones in rabbits, but very little increase in rats (Gauthaman & Ganesan 2008).

In combination
A mixture of nine oriental herbs, including tribulus, was evaluated using both in vitro and in vivo experiments on laboratory animals and demonstrated an improvement in sexual activity and erectile function (Park et al 2006). It is possible that tribulus may be useful in mild-to-moderate cases of erectile dysfunction; however, further clinical testing is required.

Oestrogenic
Saponins from tribulus appear to increase follicle stimulating hormone (FSH) in women, which in turn increase levels of oestradiol (Mills & Bone 2000). The primary site of action of steroidal saponins is probably the hypothalamus (Trickey 1998).

Antimicrobial
Antimicrobial activity of organic and aqueous extracts from fruits, leaves and roots of *Tribulus terrestris* were tested. The most active extract against both gram-negative and gram-positive bacteria was ethanol extract from the fruits against *Bacillus subtilis*, *Bacillus cereus*, *Corynebacterium diphtheriae* and *Proteus*

vulgaris. The strongest antifungal activity was against *Candida albicans* (Al-Bayati & Al-Mola 2008).

Diuretic

A large oral dose of 5 g/kg tribulus was shown to have greater diuretic activity than frusemide 120 mg/kg in vivo (Al Ali et al 2003).

Urolithic

Wth regard to kidney stones, tribulus has been found to decrease the amount of urinary oxalate in rats (Sangeeta et al 1994) and produce significant dose-dependent protection against experimentally induced uroliths in animal studies (Anand et al 1994, Sangeeta et al 1994). Experimental studies further found that tribulus was effective in preventing the deposition of crystals on glass beads in the urinary bladder of rats, dissolving phosphate-type calculi in an in vitro model, and dissolving uric acid and cystine stones to some extent (Prasad & Bharathi 2007). In vitro studies using human urine suggests that the diuretic properties of tribulus may be the most crucial mechanism for preventing urinary stone formation (Joshi et al 2005).

Antispasmodic

A dose-dependent antispasmodic activity causing a significant decrease in peristaltic movements has been demonstrated with the isolated saponin content of tribulus (Arcasoy et al 1998).

Cardioprotective activity

Tribulus is shown to have some cardioprotective actions (Ojha et al 2008). A Chinese report of successful treatment of angina pectoris with the saponin content of tribulus suggests that the preparation dilates coronary arteries and improves coronary circulation (Wang et al 1990). A triterpene saponin of tribulus may play a role in cardiocyte survival during chemical hypoxia–ischaemia as demonstrated in vitro (Sun et al 2008).

In another study 10 mg/kg/day of the aqueous extract of the fruit has shown antihypertensive effects in an animal trial when compared to control. The authors concluded that effects are possibly due to inhibition of angiotensin-converting enzyme (ACE) activity (Sharifi et al 2003). More recent research demonstrates that the antihypertensive effect appears to result from a direct arterial smooth muscle relaxation possibly involving nitric oxide release and membrane hyperpolarisation (Phillips et al 2006). Tribulus saponins not only lowered serum lipidaemia, but also relieved left ventricular remodelling, and improved cardiac function in the early stage after myocardial infarct in a hyperlipaemia mouse model (Guo et al 2007). The mechanism of action is suggested to be a reduction in cardiac muscle cell apoptosis by regulating protein expressions (Guo et al 2006).

OTHER ACTIONS

Experiments with healthy mice have found that *Tribulus terrestris* significantly inhibits gluconeogenesis, influences glycometabolism and reduces triglyceride and total cholesterol levels (Li et al 2001). Tribulus demonstrates some protection against oxidative stress in rats with induced diabetes (Amin et al 2006) and the saponins are found to have a hypoglycaemic action.

An in vitro test has also identified COX-2 inhibition activity (Hong et al 2002), suggesting possible anti-inflammatory actions. An animal study using a percolated extract of the fruits of tribulus at a dose of 100 mg/kg showed a significant analgesic effect compared to the control group with a lower gastric ulcerogenecity than indomethacin (Heidari et al 2007).

Two isolated constituents, tribulosin and beta-sitosterol-D-glucoside, have shown anthelmintic activity in vitro against *Caenorhabditis elegans* (Deepak et al 2002).

Of eight steroid saponins tested, two showed potent antifungal activity against *Candida albicans*, with one, TTS-12, demonstrating its ability to decrease virulence and destroy the cell membrane (Zhang et al 2005).

Protection against mercury-induced nephrotoxicity was demonstrated with 7 days administration of tribulus fruit extract (6 mg/kg body weight) in an animal study (Kavitha & Jagadeesan 2006).

CLINICAL USE

Aphrodisiac

The observed pharmacological effects on androgen status provide a theoretical basis for this activity, but little clinical testing has been conducted.

Results from a 2002 animal study have produced positive results suggestive of aphrodisiac activity (Gauthaman et al 2002). The study compared the effects of subcutaneous testosterone, an orally administered tribulus extract containing protodioscin (45% dry weight) or placebo over 8 weeks in castrated rodents. Both testosterone and tribulus treatments significantly improved sexual behaviour compared with controls, although testosterone was the more effective treatment.

A follow-up study by the same research team added further data (Gauthaman et al 2003). In this study, rats were treated with 2.5, 5 and 10 mg/kg once daily for 8 weeks. The results showed a considerable increase in sexual behaviour and slight weight gain compared to controls. Interestingly, the results were more pronounced at the lower dose range.

Despite positive data from animal studies, a recent small controlled clinical trial of tribulus in young men aged between 20 and 36 years showed no statistical increase in testosterone levels in the treated group (Neychev & Mitev 2005). The men were divided into two treatment groups (each n = 7) and one control group (n = 7). One group was given 10 mg/kg and the other 20 mg/kg per day divided into three even doses for 4 weeks. There was no significant change in testosterone, androstenedione or luteinising hormone.

Ergogenic aid

Tribulus has been touted as a natural anabolic supplement or ergogenic aid, capable of producing large gains in strength and lean muscle mass in 5–28 days. The observed pharmacological effects

on androgen status provide a theoretical basis for this activity; however, clinical trials have produced disappointing results.

A small, randomised, placebo-controlled study found that treatment with tribulus (3.21 mg/kg body weight daily) had no effects on body composition and exercise performance in resistance-trained men after 8 weeks (Antonio et al 2000). The study has been criticised by some athletes, as the dose of tribulus tested was very low and not indicative of the doses used in real life. A more recent RCT by Rogerson et al compared the effects of tribulus extract (450 mg/day) to placebo in 22 Australian elite male rugby league players during their preseason training period. The double study was conducted over 5 weeks and found that muscular strength and fat-free mass increased significantly in both groups, with no advantage seen for tribulus treatment. Additionally, no significant differences were seen for urinary testosterone/epitestosterone ratio compared with placebo. Once again, the trial has been criticised as using subtherapeutic doses which do not reflect manufacturer recommendations or current use (Rogerson et al 2007).

Menopausal symptoms

Saponins from tribulus appear to increase FSH in women, which in turn increase levels of oestradiol (Mills & Bone 2000). The primary site of action of steroidal saponins is probably the hypothalamus (Trickey 1998). In postmenopausal women, steroidal saponin-containing herbs like tribulus have been used to alleviate oestrogen withdrawal symptoms. Clinical studies are unavailable to determine whether the effect is significant.

Kidney stones

A human trial was conducted with a herbal combination containing *Tribulus terrestris* and another Ayurvedic herb, *Bergenia ligulata*, in the treatment of 14 patients with renal calculi and 16 patients with ureteric calculi; 28.57% of patients with renal calculi and 75% patients with ureteric calculi passed their calculi completely and in other patients, there was a marked or partial expulsion of calculi along with changes in the shapes and sizes of calculi (Prasad & Bharathi 2007). The role of tribulus in achieving these results is unknown.

OTHER USES

Traditionally, the acidic fruits are thought to be cooling and are used for painful micturition, urinary disorders, kidney stone prevention and impotence, whereas the leaves are thought to possess tonic, diuretic and anti-inflammatory properties and are used to increase menstrual flow. Interestingly, preliminary research into the pharmacological actions of tribulus or its constituents provides some support for several of these uses.

DOSAGE RANGE

In Australia, preparations containing both the fruit and the root are available that are standardised to saponin content. As no clinical studies are available, the manufacturers' recommended dose is included here, which is 2–30 g/day.

- Leaf: 750–1500 mg/day of extract standardised to contain 45% protodioscin.

TOXICITY

Although toxicity levels in humans are not known, extensive grazing on tribulus by sheep produces a syndrome known as 'staggers', which is characterised by nervous and muscular locomotor disturbances (Bourke 1984). Outbreaks are repeatedly associated with drought periods during which sheep graze on large areas of *Tribulus terrestris* for many months at a time (Bourke 1995, Glastonbury et al 1984). Investigation with isolated harmane and norharmane found naturally in tribulus have found these constituents to be responsible for the 'staggers' syndrome (Bourke et al 1992).

Hepatogenous photosensitivity has also been reported among sheep grazing on *Tribulus terrestris* for long periods (Bourke 1984, Glastonbury et al 1984, McDonough et al 1994, Miles et al 1994, Tapia et al 1994, Wilkins et al 1996). A small animal study examined the clinical, laboratory and pathological findings of this disease in sheep and concluded that tribulus was responsible for hepatogenous photosensitivity (Aslani et al 2003). Laboratory and pathology tests found significantly increased white blood cells, bilirubin, total serum protein and plasma fibrinogen, and histological findings showed crystalloid materials in the bile ducts with hepatocyte degeneration. A year later, the same research team found very similar results in goats (Aslani et al 2004).

ADVERSE REACTIONS

Gastrointestinal disturbance may occur in sensitive individuals due to the saponin content.

SIGNIFICANT INTERACTIONS

Controlled studies are not available and currently no interactions are known.

PRACTICE POINTS/PATIENT COUNSELLING

- Tribulus has been used traditionally in various parts of the world to treat colicky spasms, diarrhoea, cardiovascular disease and various kidney disorders, including kidney stones, and as an insect repellent.
- Tribulus has not undergone significant clinical testing, so much information is speculative and based on animal and test tube studies.
- Popular as an aphrodisiac, some research suggests that it increases levels of DHEA, testosterone and NO release, providing a theoretical basis for this activity. Until controlled studies are available, it is uncertain whether these effects are clinically significant.
- Tribulus is also popular among athletes as an ergogenic aid and to increase muscle strength; however, clinical studies using low-dose tribulus have not supported this use. Larger controlled studies testing higher doses that are reflective of real-world use are required to determine its efficacy.

CONTRAINDICATIONS AND PRECAUTIONS

People with androgen-sensitive tumours should avoid use.

PREGNANCY USE

Not to be used in pregnancy.

PATIENTS' FAQs

What will this herb do for me?

Preliminary research suggests that this herb increases androgen levels and improves sexual function, but human studies are not available to confirm these effects.

When will it start to work?

This is unknown.

Are there any safety issues?

Pregnant and lactating women and people with androgen-sensitive tumours should avoid use.

Turmeric

HISTORICAL NOTE Turmeric is a perennial herb, yielding a rhizome that produces a yellow powder that gives curry its characteristic yellow colour and is used to colour French mustard and the robes of Hindu priests. Turmeric was probably first cultivated as a dye, and then as a condiment and cosmetic. It is often used as an inexpensive substitute for saffron in cooking and in the 13th century Marco Polo marvelled at its similarities to saffron. Both Indian Ayurvedic and Chinese medicines use turmeric for the treatment of inflammatory and digestive disorders and turmeric has also been used in tooth powder or paste. Research has focused on turmeric's antioxidant, hepatoprotective, anti-inflammatory, anticarcinogenic and antimicrobial properties, in addition to its use in cardiovascular disease and gastrointestinal disorders (National Library of Medicine 2001).

COMMON NAME
Turmeric

OTHER NAMES
Chiang-huang, curcuma, curcumae longae rhizoma, curcuma rhizome, e zhu, haridra, Indian saffron, jiang huang, jiang huang curcumae rhizoma, turmeric rhizome, turmeric root, yellow root, yu jin, zedoary

BOTANICAL NAME/FAMILY
Curcuma longa (family Zingiberaceae [ginger])

PLANT PART USED
Dried secondary rhizome (containing not less than 3% curcuminoids calculated as curcumin and not less than 3% volatile oil, calculated on dry-weight basis).

CHEMICAL COMPONENTS
Turmeric rhizome contains 5% phenolic curcuminoids (diarylheptanoids), which give turmeric the yellow colour. The most significant curcuminoid is curcumin (diferuloylmethane).

It also contains up to 5% essential oil, including sesquiterpene (e.g. Zingerberene), sesquiterpene alcohols and ketones, and monoterpenes.

Turmeric also contains immune-stimulating polysaccharides, including acid glucans known as ukonan A, B and C (Evans 2002).

MAIN ACTIONS
Most research has focused on a series of curcumin constituents found in the herb. Many of the animal studies, however, involve parenteral administration and oral curcumin or turmeric is likely to be far less active because curcumin is poorly absorbed by the gastrointestinal tract and only trace amounts appear in the blood after oral intake (Ammon & Wahl 1991). Curcumin may, however, have significant activity in the gastrointestinal tract, and systemic effects may take place as a consequence of local gastrointestinal effects or be associated with metabolites of the curcuminoids.

Antioxidant
Studies have shown that turmeric, as well as curcumin, has significant antioxidant activity (Ak & Gulcin 2008, Bengmark 2006, Menon & Sudheer 2007, Shalini & Srinivas 1987, Soudamini et al 1992). Turmeric not only exerts direct free radical scavenging activity, it also appears to enhance the antioxidant activity of endogenous antioxidants, such as glutathione peroxidase, catalase and quinine reductase. Curcumin has been shown to induce phase II detoxifying enzymes (glutathione peroxidase, glutathione reductase, glucose-6-phosphate dehydrogenase and catalase) (Iqbal et al 2003). Additionally, its antioxidant effects are 10-fold more potent than ascorbic acid or resveratrol (Song et al 2001). In addition to curcumin, turmeric contains the antioxidants protocatechuic acid and ferulic acid and exhibits significant protection to DNA against oxidative damage in vitro (Kumar et al 2006).

Turmeric's antioxidant activity may mediate damage produced by myocardial and cerebral ischaemia (Al-Omar et al 2006, Fiorillo et al 2008, Shukla et al 2008) and diabetes (Farhangkhoee et al 2006, Jain et al 2006; Kowluru & Kanwar 2007). Turmeric has been shown to restore myocardial antioxidant status, inhibit lipid peroxidation and protect against ischaemia–reperfusion-induced myocardial injuries in two animal studies (Fiorillo et al 2008, Mohanty et al 2004). The mechanism is likely due to curcumin's antioxidant and anti-inflammatory effects. Curcumin has also been found to prevent protein glycosylation and lipid peroxidation caused by high glucose levels in vitro (Jain et al 2006) and to improve diabetic nephropathy (Srinivasan 2005) and retinopathy (Kowluru & Kanwar 2007). Turmeric has also been shown to suppress cataract development and collagen cross-linking, promote

wound healing, and lower blood lipids and glucose levels (Jain et al 2006, Panchatcharam et al 2006).

NF-kappa-B inhibition

The many and varied effects of curcumin may be partly associated with the inhibition of transcription factor, nuclear factor-kappa beta (NF-kappa-B), and induction of heat shock proteins. NF-kappa-B is a transcription factor pivotal in the regulation of inflammatory genes and is also closely associated with the heat shock response, which is a cellular defence mechanism that confers broad protection against various cytotoxic stimuli. Inhibition of NF-kappa-B may reduce inflammation and protect cells against damage (Chang 2001) and curcumin has been found to attenuate experimental colitis in animal models through a mechanism correlated with the inhibition of NF-kappa-B (Salh et al 2003). The clinical significance of this is unclear.

Anti-inflammatory

There have been a large number of studies examining the anti-inflammatory effects of curcumin. Turmeric is a dual inhibitor of the arachidonic acid cascade. Curcumin has been shown to exert anti-inflammatory effects via phospholipase, lipo-oxygenase, COX-2, leukotrienes, thromboxane, PGs, NO, collagenase, elastase, hyaluronidase, monocyte chemoattractant protein-1, IFN-inducible protein, TNF and IL-12 (Chainani-Wu 2003, Lantz et al 2005, Rao 2007). Due to its anti-inflammatory effects, curcumin has shown promise in many chronic disorders such as arthritis, colitis, allergies, arteriosclerosis, diabetes, respiratory disorders, hepatic injury, pancreatic disease, intestinal disorders, eye diseases, neurodegenerative diseases and various cancers (Aggarwal et al 2007, Bengmark 2006).

The anti-inflammatory effect of curcumin was tested in adjuvant-induced chronic inflammation rats which found that curcumin significantly reduced C-reactive protein, TNF-alpha, IL-1 and NO, with no significant changes observed in PGE_2 and leukotriene B4 levels or lymphocyte proliferation (Banerjee et al 2003). Curcumin has also been shown to inhibit inflammation in experimental pancreatitis via inhibition of NF-kappa-B and activator protein-1 in two rat models (Gukovsky et al 2003).

Gastrointestinal effects

Hepatoprotective

Extracts of both turmeric and curcumin have been found to prevent and improve carbon tetrachloride-induced liver injury both in vivo and in vitro (Abu-Rizq et al 2008, Deshpande et al 1998, Fu et al 2008, Kang et al 2002, Wu et al 2008), curcumin also protects against dimethylnitrosamine-induced liver injury (Farombi et al 2008), reverses aflatoxin-induced liver damage in experimental animals (Soni et al 1992) and effectively suppresses the hepatic microvascular inflammatory response to lipopolysaccharides in vivo (Lukita-Atmadja et al 2002). An ethanol soluble fraction of turmeric was shown to contain three antioxidant compounds, curcumin, demethoxycurcumin and bisdemethoxycurcumin, which exert similar hepatoprotective activity to silybin and silychristin in vitro (Song et al 2001).

Several different mechanisms may contribute to turmeric's hepatoprotective activity. Curcumin has been shown to prevent lipoperoxidation of subcellular membranes in a dosage-dependent manner, due to an antioxidant mechanism (Quiles et al 1998) and turmeric may also protect the liver via inhibition of NF-kappa-B (see above), which has been implicated in the pathogenesis of alcoholic liver disease. Curcumin also appears to chelate hepatic and serum iron in vivo (Jiao et al 2006, 2008). Iron is pro-oxidant to the liver, which may be problematic during hepatic disease. Recent research also suggests that curcumin may be useful in preventing hepatic fibrosis caused by chronic liver disease (Fu et al 2008, O'Connell & Rushworth 2008). Curcumin also blocked endotoxin-mediated activation of NF-kappa-B and suppressed the expression of cytokines, chemokines, COX-2 and iNOS in Kupffer cells (Nanji et al 2003).

Cholagogue and hypolipidaemic

Turmeric extract or curcumin extract has shown dose-dependent hypolipidaemic activity in vivo (Asai & Miyazawa 2001, Babu & Srinivasan 1997, Keshavarz 1976, Manjunatha & Srinivasan 2007a, 2007b, Ramirez-Tortosa et al 1999, Soudamini et al 1992). One in vivo study suggests that curcumin may stimulate the conversion of cholesterol into bile acids, and therefore increase the excretion of cholesterol (Srinivasan & Sambaiah 1991). A further study demonstrated that supplementation with turmeric reduces fatty streak development and oxidative stress (Quiles et al 2002). Curcumin also increases LDL receptor mRNA (Peschel et al 2007). Oral curcumin has also been shown to stimulate contraction of the gall bladder and promote the flow of bile in healthy subjects (Rasyid & Lelo 1999).

Antispasmodic

Curcuminoids exhibit smooth muscle relaxant activity possibly mediated through calcium channel blockade, although additional mechanisms cannot be ruled out (Gilani et al 2005). Curcuminoids produced antispasmodic effects on isolated guinea pig ileum and rat uterus by receptor-dependent and independent mechanisms (Itthipanichpong et al 2003).

Cancer

Curcumin has been studied for its wide-ranging effects on tumorigenesis, angiogenesis, apoptosis and signal transduction pathways (Gururaj et al 2002, Mohan et al 2000, Thaloor et al 1998). It is known to inhibit oncogenesis during both the promotion and the progression periods in a variety of cancers (Anto et al 1996, Kuttan et al 1985, Menon et al 1999, Ruby et al 1995). Curcumin was found to possess chemopreventive effects against skin cancer, stomach cancer, colon cancer, prostate cancer, breast cancer and oral cancer in mice.

Chemoprevention

Chemoprevention refers to reversing, suppressing or preventing the process of carcinogenesis. Carcinogenesis results from the accumulation of multiple sequential mutations and alterations in nuclear and cytoplasmic molecules, culminating in invasive neoplasms. These events have traditionally been separated into three phases: initiation, promotion and progression. Typically, initiation is rapid, whereas promotion and progression can take many years. Ultimately, chemoprevention aims at preventing the growth and survival of cells already committed to becoming malignant (Gescher et al 1998, 2001).

Curcumin inhibits the invasion, proliferation and metastasis of various cancers in vivo (Kunnumakkara et al 2008). Curcumin has been found to effectively block carcinogen-induced skin (Azuine & Bhide 1992), colon (Rao et al 1995a, 1995b, 1995c, 1999) and liver (Chuang et al 2000) carcinogenesis in animals. It has been suggested that the chemoprotective activity of curcumin occurs via changes in enzymes involved in both carcinogen bioactivation and oestrogen metabolism. This is supported by the findings that curcumin treatment produced changes in CYP1A, CYP3A and GST in mice (Valentine et al 2006) and alleviated the CCl_4-induced inactivation of CYPs 1A, 2B, 2C and 3A isozymes in rats, possibly through its antioxidant properties, without inducing hepatic CYPs (Sugiyama et al 2006).

Oral curcumin inhibited chemically induced skin carcinogenesis in mice (Huang et al 1992) and curcumin prevented radiation-induced mammary and pituitary tumours in rats (Inano & Onoda 2002). Curcumin and genistein (from soybeans) inhibited the growth of oestrogen-positive human breast MCF-7 cells induced individually or by a mixture of the pesticides endosulfane, dichlorodiphenyltrichloroethane (DDT) and chlordane, or 17-beta oestradiol (Verma et al 1997). Another study found that curcumin inhibited breast cancer metastases in immunodeficient animals (Bachmeier et al 2007). This may be due to curcumin's ability to reduce NF-kappa-B and therefore downregulate the two inflammatory cytokines CXCL1 and -2 (Bachmeier et al 2008).

Apoptosis

Apoptosis (programmed cell death) plays a crucial role in regulating cell numbers by eliminating damaged or cancerous cells. Curcumin has been shown to induce apoptosis in many different cancer cell lines, including breast, leukaemia, lymphoma, melanoma, ovarian, colorectal, lung and pancreatic in vitro (Kim et al 2001, Kuo et al 1996, Li et al 2007, Lin et al 2007, Lev-Ari et al 2006, Marin et al 2007, Skommer et al 2007, 2006, Tian et al 2008). Curcumin has also increased apoptosis in breast and ovarian cancers in vivo (Bachmeier et al 2007, Lin et al 2007). Curcumin has been demonstrated to induce apoptosis in human basal cell carcinoma cells associated with the p53 signalling pathway, which controls intracellular redox status, levels of oxidation-damaged DNA and oxidative stress-induced apoptosis (Jee et al 1998). Curcumin has also been found to induce apoptosis in human mutant p53 melanoma cell lines and block the NF-kappa-B cell survival pathway and suppress the apoptotic inhibitor known as XIAP. Because melanoma cells with mutant p53 are strongly resistant to conventional chemotherapy, curcumin may overcome the chemoresistance of these cells and provide potential new avenues for treatment (Bush et al 2001).

Curcumin has also been found to inhibit prostate cancer cell growth in mice (Dorai et al 2001) and decrease proliferation and induce apoptosis in androgen-dependent and androgen-independent prostate cancer cells in vitro. This was found to be mediated through modulation of apoptosis suppressor proteins and interference with growth factor receptor signalling pathways (Dorai et al 2000). In a further study with rats, however, curcumin did not prevent prostate carcinogenesis (Imaida et al 2001).

Antiproliferative

Reduction in proliferation and/or increased apoptosis will lead to tumour regression; however, a more potent effect will be achieved if the two mechanisms occur simultaneously. Curcumin has been shown to do this. The inhibition of cell proliferation is partly related to inhibition of various kinases, such as protein kinase and phosphorylase kinase (Reddy & Aggarwal 1994), and inhibition of several oncogenes and transcription factors. For example, turmeric inhibited epidermal growth factor receptor (EGF-R) signalling via multiple mechanisms, including downregulation of the EGF-R protein, inhibition of intrinsic EGF-R tyrosine kinase activity and inhibition of ligand-induced activation of the EGF-R (Dorai et al 2000). These mechanisms may be particularly important in preventing prostate cancer cells from progressing to a hormone refractory state (Dorai et al 2000). Curcumin has also been found to suppress the growth of multiple breast cancer cell lines and deplete p185neu, the protein product of the HER2/neu proto-oncogene that is thought to be important in human carcinogenesis (Hong et al 1999).

Antimetastatic

Curcumin demonstrated the ability to reduce lung metastases from melanoma cells in mice. The activity of curcumin is varied.

- In cell adhesion assays, curcumin-treated cells showed a dose-dependent reduction in their binding to four extracellular matrix proteins (binding to proteins is associated with the spreading of the cancer). Another study found that curcumin effectively suppressed COX-2, vascular endothelial growth factor and intercellular adhesion molecules, whilst enhancing the expression of antimetastatic proteins, tissue inhibitor metalloproteases-2, non-metastatic gene 23 and E-cadherin a transmembrane protein that plays an important role in cell adhesion (Kuttan et al 2007).
- Curcumin-treated cells showed a marked reduction in the expression of integrin receptors (integrins functionally connect the cell interior with the extracellular matrix, another process necessary for metastases).

Chemotherapy

Curcumin enhanced the cytotoxicity of chemotherapeutic agents in prostate cancer cells in vitro by inducing the expression of certain androgen receptor and transcription factors and suppressing NF-kappa-B activation (Hour et al 2002). Curcumin enhanced the antitumour effect of cisplatin against fibrosarcoma (Navis et al 1999), fluorouracil and oxaliplatin in colorectal cancer (Du et al 2006, Li et al 2007) and gemcitabine and paclitaxel in bladder cancer (Kamat et al 2007). Curcumin also attenuated multidrug resistance in a non-small cell lung cancer cell line (Andjelkovic et al 2008) and acted as a radiosensitiser for cervical cancer in vitro (Javvadi et al 2008).

Curcumin, however, was found to significantly inhibit cyclophosphamide-induced tumour regression in an in vivo model of human breast cancer. It is suspected that this occurred as a result of inhibition of free radical generation and blockade of JNK function. As such, curcumin intake should be limited in people undergoing treatment for breast cancer with cyclophosphamide until further investigation can clarify the significance of these findings (Somasundaram et al 2002).

Immunomodulation

Curcumin administration was found to significantly increase the total white blood cell count and circulating antibodies in mice. A significant increase in macrophage phagocytic activity was also observed in curcumin-treated animals (Antony et al 1999). However, curcumin has also been demonstrated to have some immunosuppressive activity. Curcumin inhibits PAR2- and PAR4-mediated human mast cell activation by blocking the ERK pathway (Baek et al 2003).

An in vivo study using a cardiac transplant model found that curcumin also significantly reduced expression of IL-2, IFN-gamma and granzyme B (a serine protease associated with the activity of killer T-lymphocytes and NK cells) and increased mean survival time. Curcumin was further shown to work synergistically with the antirejection drug, cyclosporine (Chueh et al 2003).

Curcumin also modulates other interleukins and has been shown in vitro to be a potent inhibitor of the production of the pro-inflammatory cytokine IL-8, thereby reducing tumour growth and carcinoma cell viability. Curcumin not only inhibited IL-8 production but also inhibited signal transduction through IL-8 receptors (Hidaka et al 2002) and to inhibit cell proliferation, cell-mediated cytotoxicity and cytokine production most likely by inhibiting NF-kappa-B target genes (Gao et al 2004).

Cardiovascular effects

Antiplatelet

Curcumin has been shown to inhibit platelet aggregation in vivo (Chen et al 2007, Srivastava et al 1985, 1986) and in vitro (Jantan et al 2008, Srivastava 1989, Srivastava et al 1995). The anticoagulant effect of curcumin is weaker than that of aspirin, which is four-fold more potent than curcumin in treatment of collagen- and noradrenalin-induced thrombosis. Curcumin 100 mg/kg and aspirin 25 mg/kg resulted in 60% protection from thrombosis (Srivastava et al 1985).

Anti-atherogenic

A hydro-ethanolic extract of turmeric was found to decrease LDL oxidation, have a vitamin E-sparing effect and lower the oxidation of erythrocyte and liver membranes in rabbits fed a diet high in saturated fat and cholesterol (Mesa et al 2003, Ramirez-Tortosa et al 1999). The atheroscleroprotective potential of turmeric was further demonstrated by an animal study that found turmeric lowered blood pressure and reduced the atherogenic properties of cholesterol (Zahid Ashraf et al 2005). Curcumin also inhibits the proliferation and migration of vascular smooth muscle cells in vitro (Yang et al 2006).

Many in vivo studies have investigated the effects of dietary curcumin on blood cholesterol in diabetic animals (Babu & Srinivasan 1997, Manjunatha & Srinivasan 2007a, 2007b, Pari & Murugan 2007). The two Manjunatha and Srinivasan studies found that curcumin significantly lowered plasma cholesterol but only lowered hepatic cholesterol in animals with normal baseline cholesterol. Additionally, hepatic alpha-tocopherol and glutathione levels and serum glutathione peroxidase and glutathione transferase were increased. Babu and Srinivasan also found a significant decrease in blood triglyceride and phospholipid levels (Babu & Srinivasan 1997). In a parallel study in which diabetic animals were maintained on a high cholesterol diet, curcumin lowered cholesterol and phospholipid and countered the elevated liver and renal cholesterol and triglyceride levels seen in the diabetic animals (Babu & Srinivasan 1997).

Wound healing

Wound healing is a highly ordered process, requiring complex and coordinated interactions involving peptide growth factors, of which transforming growth factor-beta (TGF-beta) is one of the most important. Nitric oxide is also an important factor in healing, and its production is regulated by iNOS. Topical application of curcumin accelerated wound healing in normal and diabetic rats. The wound healing is partly associated with the regulation of the growth factor TGF-beta-1 and iNOS (Mani et al 2002). Curcumin's wound healing ability has been confirmed in several other animal studies (Sidhu et al 1998, 1999). Wounds of animals treated with curcumin showed earlier re-epithelialisation, improved neovascularisation, increased migration of various cells, including dermal myofibroblasts, fibroblasts and macrophages into the wound bed, and a higher collagen content (Sidhu et al 1999). It appears to be effective when used orally or as a local application.

Curcumin has also demonstrated powerful inhibition against hydrogen peroxide damage in human keratinocytes and fibroblasts (Phan et al 2001) and pretreatment with curcumin significantly enhanced the rate of wound contraction, decreased mean wound healing time, increased synthesis of collagen, hexosamine, DNA and NO and improved

fibroblast and vascular densities in full thickness wounds in mice exposed to whole-body gamma-radiation (Jagetia & Rajanikant 2004).

Antimicrobial

Turmeric is used as an antimicrobial for preserving food (Jayaprakasha et al 2005) and has been found to have antifungal activity, as well as inhibiting aspergillus growth and aflatoxin production in feeds (Gowda et al 2004).

Curcumin has also been found to have dose-dependent, antiprotozoan activity against *Giardia lamblia* with inhibition of parasite growth and adherent capacity, induction of morphological alterations and apoptosis-like changes in vitro (Perez-Arriaga et al 2006). Curcumin has also shown in vitro and in vivo activity against malaria, with inhibition of growth of chloroquine-resistant *Plasmodium falciparum* in vitro and enhancement of survival in mice infected with *P. berghei* (Reddy et al 2005).

Psoriasis

Topical curcumin reduced the severity of active, untreated psoriasis as assessed by clinical, histological and immunohistochemical criteria in an observational study of 10 patients. Curcumin was also found to decrease phosphorylase kinase, which is involved in signalling pathways, including those involved with cell migration and proliferation (Heng et al 2000). Topical administration of curcumin also induced normal skin formation in the modified mouse tail test (Bosman 1994). The effects are thought to be due to immune-modulating, anti-inflammatory and cyclo-oxygenase inhibitory actions. The downregulation of pro-inflammatory cytokines supports the view that turmeric antioxidants may exert a favourable effect on psoriasis-linked inflammation. Moreover, because IL-6 and IL-8 are growth factors for keratinocytes, their inhibition by those antioxidants may reduce psoriasis-related keratinocyte hyperproliferation (Miquel et al 2002).

OTHER ACTIONS

Curcumin's anti-inflammatory and antioxidant actions may be useful in preventing neurodegenerative diseases, such as Alzheimer's dementia and Parkinson's disease, and curcumin has been found to target multiple pathogenic cascades in preclinical models (transgenic and amyloid infusion models) of AD (Cole et al 2005, Calabrese et al 2006). Curcumin has also been found to dose-dependently inhibit neuroglial proliferation, with low doses being as effective as higher doses given a longer period of treatment (Ambegaokar et al 2003). It may also enhance immune clearance of amyloidosis in the brain (Zhang et al 2006).

Curcumin had anti-asthmatic activity in animal models of induced asthma. Curcumin (20 mg/kg body weight) treatment significantly inhibited chemical (ovalbumin)-induced airway constriction and airway hyperreactivity. The results demonstrate that curcumin is effective in improving the impaired airways features in ovalbumin-sensitised guinea pigs (Ram et al 2003).

Curcumin has been found to have inhibitory effects on P-glycoprotein in numerous test tube studies (Anuchapreeda et al 2002, Limtrakul et al 2004, Nabekura et al 2005). The clinical significance of this observation has yet to be determined.

CLINICAL USE

In practice, turmeric and the various curcuminoids are used in many forms and administered via various routes. This review will focus mostly on those methods of use that are commonly used and preparations that are available over the counter (OTC), such as oral dose forms and topical applications.

Cancer

Epidemiological data suggest that curcumin reduces the rate of colorectal cancer (Hergenhahn et al 2002) and curcumin has wide-ranging chemopreventive activity in preclinical carcinogenic models (Plummer et al 2001), most notably for gastrointestinal cancers (Ireson et al 2001). To date, however, there are no controlled trials to attest to turmeric's efficacy in cancer treatment or prevention.

Curcumin appears to be a well-tolerated adjunctive treatment option for patients with pancreatic cancer. Twenty-five participants took 8 g of curcumin daily. Despite significant inter-patient variations in blood curcumin levels, NF-kappa-B, COX-2 and phosphorylated signal transducer and activator of transcription 3 were all downregulated in peripheral blood mononuclear cells (Dhillon et al 2008).

In a phase 1 study, curcumin taken orally for 3 months at a starting dose of 500 mg/day was found to produce histologic improvement in cases of bladder cancer, oral leucoplakia, intestinal metaplasia of the stomach, cervical intraepithelial neoplasm and Bowen's disease (Cheng et al 2001).

An ethanol extract of turmeric, as well as an ointment of curcumin, was found to produce remarkable symptomatic relief in patients with external cancerous lesions (Kuttan et al 1987) and there are clinical reports to suggest that curcumin could be safe and effective in the treatment of idiopathic inflammatory orbital pseudotumours (Lal et al 2000).

Dyspepsia/peptic ulcers

A randomised, controlled, double-blind, prospective, multicentre pilot study compared the effects of dried extracts of greater celandine and turmeric with placebo in 76 patients with colicky abdominal pain in the right upper quadrant due to biliary dyskinesia. Abdominal pain was reduced more quickly with active treatment; however, other symptoms such as fullness, nausea and vomiting did not respond (Niederau & Gopfert 1999). Another randomised, placebo-controlled, double-blind study that investigated the efficacy of turmeric for treatment of dyspepsia and flatulence in 116 adult patients with acidic dyspepsia, flatulent dyspepsia or atonic dyspepsia found that 87% of patients receiving turmeric responded compared to 53% receiving placebo (Thamlikitkul et al 1989).

In a study of 24 patients with duodenal or gastric ulcers varying between 0.5 and 1.5 cm in diameter, 300 mg of turmeric given five times daily, 30–60 min before meals, at 4 pm and at bedtime successfully healed 48% of ulcers after 4 weeks and 76% after 12 weeks. Of 20 patients who had erosion gastritis and dyspepsia, the same treatment produced a satisfactory reduction in abdominal pain and discomfort after the first and second week (Prucksunand et al 2001). Turmeric has also been positively compared to a liquid antacid for the treatment of gastric ulcer in a controlled clinical trial (Kositchaiwat et al 1993).

Irritable bowel disease (IBD)

Turmeric extract shows promise in the symptomatic treatment of IBD, according to a partially blinded, randomised study by Bundy et al (2004). The study of 207 volunteers with diagnosed irritable bowel syndrome (IBS) complying with the Rome II criteria were randomly assigned to receive either 72 mg or 144 mg of turmeric a day or placebo for 8 weeks (Bundy et al 2004). The group receiving the lower dose (72 mg/day) experienced a significant 53% decrease in irritable bowel symptoms, whereas higher treatment (144 mg/day) resulted in a 60% decrease when compared to placebo ($P < 0.001$). Abdominal discomfort was also reduced by 22% and 25% of patients in the 72 mg and 144 mg groups, respectively ($P < 0.001$). Approximately two-thirds of the participants in the active groups reported overall symptom improvement and had better quality-of-life scores.

Inflammatory bowel disease

An open-label pilot study has produced preliminary data to suggest that curcumin may be effective in inflammatory bowel disease (Holt et al 2005). Five patients with Crohn's disease received 360 mg of curcumin 3 times a day for 1 month, followed by 4 times a day for another 2 months. The Crohn's disease activity index (CDAI), C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) fell significantly in 4 out of 5 patients. Five patients with ulcerative proctitis were also enrolled and received 550 mg of curcumin twice a day for 1 month, then three times a day for another month. Overall, stool quality was greatly improved and frequency was significantly reduced. Two patients were able to eliminate their concomitant medications altogether, whilst another two patients were able to reduce them. The CRP and ESR also returned to within normal limits by the cessation of the study.

A randomised, double-blind, multicentre trial of 89 patients examined the efficacy of curcumin as a maintenance therapy in ulcerative colitis (Hanai et al 2006). Patients in the active group received 1 g of curcumin, twice a day with sulfasalazine or mesalazine as compared to placebo plus sulfasalazine or mesalazine. At the end of the study period, 4.65% of patients in the curcumin group relapsed during treatment as compared to 20.51% in the placebo group ($P = 0.040$). The clinical activity index ($P = 0.038$) and endoscopic index ($P = 0.0001$) were also significantly improved. This is a promising result that may have great clinical significance.

Hyperlipidaemia

Turmeric may be associated with a decrease in the risk of cardiovascular disease and an intake of 200 mg of a hydro-ethanolic extract of turmeric may decrease total blood lipid peroxides and HDL- and LDL-lipid peroxidation, as well as normalise plasma fibrinogen levels and apolipoprotein B/apolipoprotein A ratio (Miquel et al 2002).

A placebo-controlled, randomised, double-blind study investigated the effects of curcumin on the serum lipids in 36 elderly men and women (Baum et al 2007). The participants were randomised to either receive 4 g/day of curcumin, 1 g/day of curcumin or placebo for 6 months. Neither active product significantly altered triacylglycerols or cholesterol at 1 nor 6 months; however, the concentrations of plasma curcumin and serum cholesterol were positively and significantly correlated. This appears to indicate that curcumin may be a mild hypocholesterolaemic agent; however, larger trials are needed.

In an open trial, 10 healthy volunteers received 500 mg/day of curcumin for 7 days. A significant decrease in the level of serum lipid peroxides (33%), increase in HDL cholesterol (29%) and a decrease in total serum cholesterol (11.63%) were noted. It also reduced serum lipid peroxides (Soni & Kuttan 1992). In a subsequent study, a 45-day intake (by healthy individuals 27–67 years of age) of a turmeric hydro-alcoholic extract at a daily dose equivalent to 20 mg of curcumin resulted in a significant decrease in serum lipid peroxides (Ramirez-Bosca et al 1995). A daily intake of turmeric equivalent to 20 mg of the phenolic antioxidant curcumin for 60 days also decreased peroxidation of both HDL and LDL in 30 healthy volunteers ranging in age from 40 to 90 years. The effect was quite striking in the persons with high baseline values of peroxidised compounds in these lipoproteins, although no apparent change took place in the persons having low baseline values (Ramirez et al 1997).

Psoriasis

A phase 2, non-blinded, open-label trial investigated the effect of curcuminoid C3 complex (500 mg, 3 capsules 3 times a day) in 12 patients with plaque psoriasis for 12 weeks followed by a 4-week observation period (Kurd et al 2008). Results were poor with the intention-to-treat analysis response rate only reaching 16.7%. Of the eight patients who completed the trial the two participants who responded achieved good results (83% and 88% improvement in symptoms), however this could be due to a placebo effect. Overall, the medication was well tolerated with only mild side effects being reported, due to either gastrointestinal upset or hot flushing.

Arthritis

In a randomised, controlled double-blind study, curcumin 1200 mg/day was compared with phenylbutazone in subjects with rheumatoid arthritis

(RA). Curcumin was found to be effective in improving morning stiffness, walking time and joint swelling; however, the effects of phenylbutazone were stronger (Deodhar et al 1980).

Curcumin combined with Boswellia, Withania and zinc produced a significant drop in pain and disability in osteoarthritis (OA) of the knee in a randomised, double-blind, placebo-controlled crossover study of 42 patients (Kulkarni et al 1991); however, the contribution of curcumin to these results is unknown.

OTHER USES

Chronic anterior uveitis

An open study of 32 patients found that orally administered curcumin improved symptoms and reduced recurrences of chronic anterior uveitis (a condition often associated with other autoimmune disorders) with an efficacy comparable to corticosteroid therapy, yet without significant side effects (Lal et al 1999).

Oral submucous fibrosis

Turmeric extract 3 g, oil 600 mg and oleoresin 600 mg effectively relieved symptoms and reduced the number of micronuclei (a sign of damage to the DNA and chromosomal integrity) in circulating lymphocytes and oral mucosal cells in patients with oral submucous fibrosis, a debilitating disease of the oral cavity mainly caused by chewing betel nut or tobacco (Hastak et al 1997).

DOSAGE RANGE

Internal use

- Powdered turmeric: 1.5–3 g/day in water or cooking.
- Liquid extract (1:1) in 45% ethanol: 5–15 mL/day.
- Powdered extract standardised to 95% curcumin: 100–300 mg/day. Higher doses used for arthritis and cancer.

External use

- Turmeric powder of standardised powdered extract applied as a paste or poultice — half cup of turmeric combined with 1 teaspoon of carbonate of soda and then mixed with hot water to make a paste; spread on gauze and apply to affected area.

ADVERSE REACTIONS

The safety of curcumin is demonstrated by the fact that it has been consumed for centuries at levels of up to 10 mg/day by people in certain countries (Ammon & Wahl 1991). Curcumin was not toxic to humans in doses up to 8000 mg/day when taken by mouth for 3 months (Cheng et al 2001). Multiple other human trials have also found it to be safe with no alteration of liver or renal function tests (Chainani-Wu 2003, Prucksunand et al 2001, Ramirez-Bosca et al 1995, Ramirez et al 1997, Sharma et al 2001).

Large doses of turmeric powder may cause gastrointestinal irritation in some persons (Shankar et al 1980) and very high dosages have been shown to reduce fertility in male rats (human equivalent doses would be 35 g turmeric/70 kg adult) (Bhagat & Purohit 2001). Normal therapeutic dosages of turmeric are not expected to affect fertility. Contact dermatitis has been reported (Hata et al 1997), as has a single case of anaphylaxis (Robinson 2003).

SIGNIFICANT INTERACTIONS

Controlled studies are not available, so interactions are based on evidence of activity and are largely theoretical and speculative.

Antiplatelet drugs

Turmeric has a theoretical interaction with antiplatelet drugs; antiplatelet properties have been demonstrated for curcumin, therefore it may produce an additive effect. The clinical significance of this interaction is unclear and likely to be dose-dependent.

Anticoagulants

Theoretically, high-dose turmeric preparations may increase the risk of bleeding when used together with anticoagulant drugs — caution is advised.

Cyclophosphamide

Animal studies suggest that curcumin may reduce drug efficacy — avoid.

CONTRAINDICATIONS AND PRECAUTIONS

Turmeric is contraindicated in bile duct obstruction (Blumenthal et al 2000) and high doses are probably best avoided in males and females wanting to conceive.

Curcumin is also contraindicated in breast cancer patients treated with cyclophosphamide until the significance of an in vivo model of breast cancer, which found that curcumin reduced the tumour regression effects of chemotherapy, is clarified (Somasundaram et al 2002).

Due to antiplatelet activity and possible increased risk of bleeding, use of concentrated extracts should be suspended 1 week prior to major surgery; however, usual dietary intakes are likely to be safe.

PREGNANCY AND LACTATION USE

When used as a spice, this herb is most likely to be safe; however, the safety of therapeutic doses has not been established. Turmeric has been demonstrated not to be mutagenic in vitro (Nagabhushan & Bhide 1986) or to be teratogenic in mice (Garg 1974, Vijayalaxmi 1980). Constituents and/or metabolites of turmeric and curcumin were transferred to suckling pups, but no ill effect on the offspring was reported.

PATIENTS' FAQs

What will this herb do for me?

In countries where people use turmeric extensively in cooking (generally in curries), the intake seems to be associated with a lower level of certain chronic conditions, possibly including cancer, gastrointestinal diseases and arthritis. There have been some encouraging studies supporting this.

When will it start to work?

In some studies, the effect began to be noticed after 2 weeks. However, as most of the conditions where turmeric may be beneficial are chronic in nature, treatment with turmeric should be considered long term.

Are there any safety issues?

Turmeric is considered very safe at normal dietary or therapeutic dosages with turmeric extracts. High doses are generally not recommended during pregnancy or for those wanting to conceive.

PRACTICE POINTS/PATIENT COUNSELLING

- In Ayurvedic medicine, turmeric is used to strengthen the overall energy of the body, relieve gas, dispel worms, improve digestion, regulate menstruation, dissolve gallstones, relieve arthritis and purify the blood (Blumenthal et al 2000).
- In Traditional Chinese medicine (TCM), turmeric is used for bruises, sores, ringworm, chest pain, toothache and jaundice. Turmeric was also recommended for abdominal pain, mass formation in the abdomen and amenorrhoea (Blumenthal et al 2000).
- Turmeric is commonly used in foods and is likely to be a safe and healthy addition to the diet.
- Turmeric has been shown to have antioxidant, anti-inflammatory and anti-atherosclerotic activities; however, further clinical evidence is needed before it can be recommended to treat specific conditions.
- Clinical evidence suggests that turmeric may provide benefit for people with dyspepsia, peptic ulcer, hyperlipidaemia and arthritis and there is emerging evidence to suggest that turmeric may help prevent a number of cancers as well as being useful as an adjuvant in cancer treatment.

Tyrosine

HISTORICAL NOTE Tyrosine has been used by the military in the USA and the Netherlands to counter the stressful effects of cold, prolonged and excessive physical activity. It also appears to improve cognition and performance in soldiers under psychologically stressful conditions and has been scientifically shown to improve physical and mental endurance (Deijen et al 1999).

BACKGROUND AND RELEVANT PHARMACOKINETICS

Tyrosine is a conditionally essential aromatic amino acid. It can be taken through the diet or synthesised in the body from phenylalanine, except in phenylketonurics. L-Tyrosine is absorbed in the small intestine by active transport and transported to the liver where it is involved in a number of biochemical reactions, such as protein synthesis and oxidative catabolic reactions. L-Tyrosine that is not metabolised in the liver is distributed via the systemic circulation to various tissues in the body where it is involved in the synthesis of a number of catecholamines and hormones (Hendler & Rorvick 2001), incorporated into protein structures or deaminated for gluconeogenesis. Peak plasma tyrosine

levels occur 2 hours after administration and remain elevated for 6–8 hours (Glaeser et al 1979).

There is some question as to tyrosine's ability to cross the blood–brain barrier and this may explain some of the negative results demonstrated in clinical trials. Proper flow is dependent upon the ratio of tyrosine to other large neutral amino acids (phenylalanine, tryptophan, methionine, leucine, isoleucine and valine) that compete for uptake by neurons (Glaeser et al 1979). A rat study has demonstrated that combining the essential fatty acid alpha-linolenic acid with L-tyrosine, via a special bond, produces an active biological molecule with potent dopaminergic activity, suggesting that alpha-linolenic acid may play a dual role as a carrier for tyrosine and as a membrane- and receptor-improving agent (Yehuda 2002).

CHEMICAL COMPONENTS

L-Tyrosine is the form generally used. Tyrosine is also known as beta-(para-hydroxyphenyl) alanine, alpha-amino-para-hydroxyhydrocinnamic acid and *(S)*-alpha-amino-4-hydroxybenzenepropanoic acid.

FOOD SOURCES

Good dietary sources include soy products, chicken, fish, almonds, avocados, bananas, dairy products, meat, eggs, nuts, beans, oats, wheat, lima beans, pumpkin seeds, sesame seeds and fermented foods such as yoghurt and miso.

DEFICIENCY SIGNS AND SYMPTOMS

The following have been associated with low levels of tyrosine:

- depression
- low blood pressure
- low body temperature
- restless legs syndrome
- hypothyroidism.

MAIN ACTIONS

Neurotransmitter and hormone production

Many of the pharmacological actions of tyrosine relate to its role as a precursor for a number of neurotransmitters and hormones.

Elevating tyrosine concentrations in brain catecholamine neurons (particularly dopamine and noradrenaline neurons) can stimulate neurotransmitter production in actively firing neurons but not in those that are quiescent or firing slowly (Fernstrom 2000).

It plays an essential role in the body as a precursor to the catecholamine neurotransmitters as illustrated below.

Phenylalanine → **Tyrosine** → L-Dopa → Dopamine → Noradrenaline → Adrenaline

Folate, vitamins B3, B6, B12 and C, iron, copper and other nutrients are required for the metabolism of tyrosine to catecholamines.

Thyroid hormones

As tyrosine is a precursor for the synthesis of thyroid hormones it is involved in the regulation of basal metabolic rate, oxygen use, cellular metabolism, growth and development (Tortora & Grabowski 1996).

Tyrosine undergoes iodination to form T_1 (mono-iodotyrosine), a second iodination produces T_2 (di-iodotyrosine) and these combine to produce the active thyroid hormones known as T_3 (tri-iodothyronine) and T_4 (tetra-iodothyronine or thyroxine) (Tortora & Grabowski 1996).

Tyrosine is also involved in the production of other compounds such as melanin, enkephalins and some types of oestrogen (Haas 1992, Tortora & Grabowski 1996).

Antioxidant

L-Tyrosine, a monophenolic amino acid, demonstrates antioxidant activity in various assays including: DPPH (1,1-diphenyl-2-picryl-hydrazyl) free radical scavenging, ABTS (2,2'-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid) radical scavenging, superoxide anion radical scavenging, hydrogen peroxide scavenging, total ferric ions reducing power and metal chelating on ferrous ions' activities, as well as inhibition of lipid peroxidation of linoleic acid emulsion (Gulcin 2007).

CLINICAL USE

Phenylketonuria

In phenylketonuria (PKU) a severe deficiency of phenylalanine hydroxylase prevents the conversion of phenylalanine to tyrosine resulting in a buildup of phenylalanine which may cause severe mental retardation and a deficiency of tyrosine. PKU is treated by restricting dietary intake of natural protein and substituting a protein source that lacks phenylalanine but is fortified with tyrosine. Unfortunately, free tyrosine supplementation has not been shown to consistently improve neuropsychologic function in PKU, which is possibly because tyrosine levels naturally fluctuate through the day and increases in plasma tyrosine levels are not sustained, so brain influx remains suboptimal despite tyrosine supplementation (Kalsner et al 2001). In practice, plasma tyrosine levels need to be monitored for diurnal variation (normal: 45 micromol/L) and biochemical evidence of tyrosine deficiency should be established before tyrosine supplementation is considered (Poustie & Rutherford 2000, van Spronsen et al 2001).

Enhanced cognition

Therapeutically, tyrosine supplements are used to enhance levels of its derivatives and, therefore, improve cognitive function.

One randomised, placebo-controlled study investigated the effects of L-tyrosine (150 mg/kg) on cognitive performance following one night's sleep loss. Supplementation was found to significantly reduce performance decline, with cognitive improvements lasting approximately 3 hours (Neri et al 1995).

RCTs comparing the effects of a balanced amino acid drink with one lacking in tyrosine and phenylalanine demonstrated that tyrosine-depleted individuals experienced impaired spatial recognition memory and spatial working memory and an increase in plasma prolactin levels (Harmer et al 2001, McTavish et al 2005), indicating a decrease in dopamine neurotransmission within the hypothalamus. Although ratings of depression and other aspects of cognitive function were unaffected, subjective feedback indicated that the participants felt better on the balanced drink (Harmer et al 2001).

Changes in tyrosine transport may also influence cognitive functioning in schizophrenia via the dopamine system (Wiesel et al 2005).

Depression

As tyrosine is a precursor to both dopamine and noradrenaline, researchers have suggested that tyrosine depletion may play a role in the pathogenesis of depression. To date studies testing this hypothesis have produced mixed results. One study found that tyrosine- and phenylalanine-depleted individuals became less content and more apathetic than those given a balanced amino acid mixture (McLean et al 2004). However, a separate study in individuals with a past history of recurrent depression found that tyrosine depletion did not alter objective or subjective measures of mood (McTavish et al 2005), although plasma prolactin levels did increase and performance on a spatial recognition memory task was impaired (McTavish et al 2005). A prospective, randomised, double-blind, placebo controlled trial of 65 subjects with major depression comparing L-tyrosine (100 mg/kg/day), imipramine (2.5 mg/kg/day) or placebo for 4 weeks failed to confirm an antidepressant effect for tyrosine (Gelenberg et al 1990).

Tyrosine may be useful in treating depression associated with a lack of noradrenaline or dopamine. One study involving patients with signs of dopamine-dependent depression (DDD) found that treatment with oral tyrosine (3200 mg/day) caused an immediate improvement in mood, as judged by clinical impression and objective test scores (Montgomery–Asperg Depression Rating Scale) and sleep parameters from day 1 of treatment (Mouret et al 1988a). It has been suggested that a subset of depression patients who fail to respond to antidepressant treatments except amphetamines may be candidates for treatment (L-Tyrosine 2007).

Attention deficit disorder

An 8-week open trial of L-tyrosine in 12 adults with attention deficit disorder (residual type) demonstrated benefits at 2 weeks, however tolerance developed after 6 weeks rendering the treatment ineffectual (Reimherr et al 1987). Previous studies had reported similar effects (Wood et al 1985).

Reward deficiency syndrome

Tyrosine depletion appears to affect reward-based processing (McLean et al 2004) and tests involving reward/punishment processing are affected by dopamine depletion (Roiser et al 2005). A lack of D_2 receptors and/or dopamine depletion states have been implicated in a number of conditions or destructive behaviours thought to be caused by poorly functioning biochemical reward systems.

Individuals tend to be at risk of multiple addictive, impulsive and compulsive behavioural problems, such as severe alcoholism, cocaine, heroin, marijuana and nicotine addiction, pathological gambling, sex addiction, chronic violence, post-traumatic stress disorder, risk-taking behaviours and antisocial behaviour. As such, the use of tyrosine as a precursor to dopamine has a theoretical basis for use in this condition (Blum et al 2000).

Reward deficiency syndrome has also been proposed as a possible mechanism explaining the tendency to drug and alcohol addiction in schizophrenia (Green et al 1999).

To date, no large controlled studies are available to determine the clinical effects of tyrosine supplementation in this condition.

Drug withdrawal

Tyrosine has been used to aid in the withdrawal of cocaine, caffeine and nicotine. Anecdotal reports suggest it is successful; however, large controlled studies are not available to determine clinical significance.

L-tyrosine supplementation has been considered because chronic cocaine use is believed to cause catecholamine depletion and cocaine withdrawal has been associated with major depression. To date, results from trials using tyrosine as a stand-alone treatment during cocaine withdrawal have produced disappointing results (Chadwick et al 1990, Galloway et al 1996). Although untested as yet, the effects of tyrosine may be of most assistance where a deficiency of dopamine D_2 receptors is suspected, such as in reward deficiency syndrome.

Stress adaptation

Physical and emotional stress can impair performance and memory. In order to reduce the adverse effects of stress on these functions, improvements in stress adaptation are sought, including through the use of supplements such as tyrosine. Tyrosine appears to enhance the release of catecholamines when neurons are firing at an increased rate due to stress, but not at their basal rates (Young 2007). Several clinical studies have explored the effects of tyrosine in volunteers exposed to stressful situations, generally producing positive results on some parameters (see 'Clinical note: allostatic responses to stress' in the Siberian ginseng monograph for more information about stress adaptation). A number of studies have been conducted by the US and Dutch military, so extrapolation to other population groups should be made with caution.

Tyrosine supplementation was found to reduce the effects of stress and fatigue on cognitive performance in a study conducted with a group of 21 cadets during a demanding military combat training course. Subjects received a protein-rich drink containing (2 g) tyrosine five times daily or a carbohydrate-rich drink with the same amount of calories (255 kcal). Assessments on day 6 of the

course showed that the tyrosine group performed better on a memory and a tracking task than the control group and further experienced a decrease in systolic blood pressure; however, no effects on mood were observed (Deijen et al 1999).

Other studies indicate that high-dose tyrosine (150 mg/kg) may also improve some aspects of performance and help sustain working memory when multi-tasking in stressful situations. One placebo-controlled trial involving 20 people found that administration of tyrosine significantly enhanced accuracy and working memory during the multiple task battery 1 hour after ingestion. However, tyrosine did not significantly alter performance on the arithmetic, visual or auditory tasks during the multiple task, or modify any performance measures during the simple task battery (Thomas et al 1999).

Cold stress

Similar results were obtained in another controlled trial that investigated the effects of tyrosine (150 mg/kg) on memory tasks in cold (4°C) conditions. Two hours after ingesting L-tyrosine, matching accuracy significantly improved in the cold and was at the same level as administration of either tyrosine or placebo at a comfortable 22°C (Shurtleff et al 1994). Two small trials have shown that tyrosine supplementation (total 300 mg/kg) alleviates working memory decrements induced by cold exposure (~10°C) (Mahoney et al 2007) and may also improve the psychomotor task of marksmanship (O'Brien et al 2007).

Other beneficial effects have been obtained with tyrosine supplementation in volunteers exposed to cold stress. A double-blind, placebo-controlled, crossover study found that tyrosine (100 mg/kg) could protect humans from some of the adverse consequences of a 4.5 hour exposure to cold and hypoxia. Tyrosine significantly decreased symptoms, adverse moods and performance impairment in subjects who exhibited average or greater responses to these environmental conditions (Banderet & Lieberman 1989).

OTHER USES

Premenstrual syndrome

Although tyrosine is used to reduce symptoms of irritability, depression and fatigue associated with PMS, this is largely based on theoretical considerations and the observation that a significant reduction in tyrosine levels occurs during the premenstrual period according to one study (Menkes et al 1994).

This study further found that tryptophan depletion caused a significant aggravation of premenstrual symptoms, particularly irritability, and symptom magnitude was correlated with reduction in tryptophan relative to other amino acids.

Reproductive effects

Although no controlled studies are available, tyrosine is sometimes used for lowered libido as it indirectly increases testosterone and dopamine levels, both factors important in this condition. Five female lambs with delayed puberty who received a single oral dose of L-tyrosine (100 mg/kg bodyweight) exhibited significantly higher progesterone concentrations than a control group. Three came into heat and two became pregnant compared to none in the control group (El-Battawy 2006).

Parkinson's disease

Administration of tyrosine has been shown to increase dopamine production in the CNS of patients with Parkinson's disease (Growdon et al 1982).

Weight loss

Tyrosine is thought to potentially suppress appetite and stimulate brown adipose tissue due to its enhancement of noradrenaline synthesis. Additionally, as a precursor for thyroid hormones it may also increase the basal metabolic rate.

Chronic fatigue syndrome

Low tyrosine levels have been identified in subjects with chronic fatigue syndrome, suggesting a possible role for supplementation in this condition (Georgiades et al 2003).

Narcolepsy

Abnormalities of the dopaminergic system are thought to be part of the underlying aetiology of this disorder, therefore tyrosine is used on the theoretical basis that an increase in dopamine levels will produce an improvement (Roufs 1990).

A randomised, double-blind placebo-controlled study of L-tyrosine (9 g/day for 4 weeks) that tests this theory has been conducted in 10 subjects with narcolepsy and cataplexy. While receiving tyrosine, subjects reported feeling less tired, less drowsy and more alert; however, ratings of daytime drowsiness, cataplexy, sleep paralysis, night-time sleep, overall clinical response, and measurements of multiple sleep latency and tests of speed and attention did not detect a significant difference with placebo (Elwes et al 1989). An earlier trial of longer duration, however, reported that within 6 months all eight participants were free from daytime sleep attacks and cataplexy (Mouret et al 1988b).

Nemaline myopathy

Five patients (4 infants and 1 adolescent) with nemaline myopathy (facial and bulbar weakness resulting in chewing and swallowing difficulties, recurrent aspiration, and poor control of oral secretions) received L-tyrosine (250 to 3000 mg/day). All infants experienced an initial decrease in sialorrhoea and an increase in energy levels. The adolescent experienced improved strength and exercise tolerance (Ryan et al 2008).

DOSAGE RANGE

- As tyrosine is considered to be a non-essential amino acid there is no specific recommended daily intake. The typical dose in clinical trials appears to be 100–150 mg/kg. Divided dosing may be beneficial as levels remain above baseline for 6-8 hours following administration.
- Depression, PMS and chronic fatigue: 500–1000 mg before meals three times daily.

- Stress: 1500 mg/day in divided doses.
- Decreased libido, Parkinson's disease, drug detoxification, and weight loss: 1–2 g/day in divided doses.
- Natural stimulant: 500–1000 mg on an empty stomach first thing in the morning.
- Alertness following sleep deprivation: 150 mg/kg/day.
- As individual sensitivity to tyrosine can vary, it is recommended to start at 100 mg/day and gradually increase dose (Cass & Holford 2001).

ADVERSE REACTIONS

Migraine headache, mild gastric upset, nausea, headache, fatigue, heartburn, arthralgia, insomnia and nervousness (Hendler & Rorvik 2001).

High blood pressure may occur in susceptive individuals — hypertensive patients taking tyrosine should be monitored closely.

SIGNIFICANT INTERACTIONS

Amphetamine, ephedrine, phenylpropanolamine

L-Tyrosine (200 and 400 mg/kg) has been shown to increase the side-effect of anorexia caused by phenylpropanolamine, ephedrine and amphetamine in a dose-dependent manner in rats (Hull & Maher 1990) — observe patients using this combination.

Antidepressant drugs

Monoamine oxidase inhibitors (MAOIs), tricyclic antidepressants or selective serotonin reuptake inhibitors (SSRIs): Theoretically, concurrent use may result in elevated blood pressure and/or enhanced antidepressant effects. In the case of MAOIs some tyrosine may be metabolised to tyramine and concurrent use with MAOIs may lead to a hypertensive crisis.

Tyrosine should be avoided unless under medical supervision.

CNS stimulants

Tyrosine is a precursor to a number of neurotransmitters so additive effects may occur — caution.

Levodopa

L-Dopa competes with tyrosine for uptake, therefore concurrent use may decrease uptake of both substances, reducing efficacy (Riederer 1980, DiPiro et al 1999, Awad 1984) — avoid unless under medical supervision.

Morphine sulfate

L-Tyrosine potentiates morphine-induced analgesia 154% in mice (Hull et al 1994). Observe patients taking tyrosine and morphine sulfate concurrently — potential beneficial interaction.

Thyroid hormone medication

Additive effects possible because tyrosine is a precursor to thyroid hormones — observe patients taking tyrosine concurrently with thyroid hormone medication.

CONTRAINDICATIONS AND PRECAUTIONS

- Malignant melanoma: a theoretical concern exists that tyrosine supplementation may promote the division of cancer cells (McArdle et al 2001). Tyrosine is contraindicated until safety is established.
- Manic conditions: due to the theoretical possibility that tyrosine may significantly increase neurotransmitter synthesis, close medical supervision is required (Cass & Holford 2001).
- Hyperthyroidism and Graves' disease: theoretically tyrosine may aggravate these conditions as it is a precursor to thyroxine (van Spronsen et al 2001).
- Alkaptonuria and tyrosinaemia (inborn errors of tyrosine metabolism).
- Hypertension: use tyrosine with caution at high dose.
- Ecstasy users should be aware that MDMA increases the concentration of tyrosine in the brain causing long-term depletion of 5-HT (Breier et al 2006).

PREGNANCY USE

High-dose supplements should be used with caution in pregnancy.

PATIENTS' FAQs

What will this supplement do for me?

Tyrosine supplementation appears to increase the levels of important brain chemicals and thyroid hormones. As such, it may elevate mood and alertness, and enhance the body's ability to deal with stress.

When will it start to work?

Although some research suggests that effects begin within 1–2 hours, it may take up to 1 week for maximal effects to be seen.

Are there any safety issues?

Theoretically, tyrosine may increase blood pressure in susceptible individuals and also interact with a number of medicines such as pharmaceutical antidepressants and thyroid treatment. It is also not recommended in pregnancy.

PRACTICE POINTS/PATIENT COUNSELLING

- Tyrosine is a conditionally essential amino acid that is ingested from the diet or produced from phenylalanine in the body.
- Many of the pharmacological actions of tyrosine relate to its role as a precursor to a number of neurotransmitters and thyroid hormones.
- Protein sources enriched with tyrosine but lacking in phenylalanine are used in PKU.
- Tyrosine supplements are used to improve cognitive function, in the management of depression or reward deficiency syndrome associated with noradrenaline or dopamine depletion, and to enhance stress adaptation systems.
- Due to its effects on neurotransmitters, it may elevate blood pressure in susceptible people when taken in high doses, and increase the effects of amphetamines, ephedrine, phenylpropanolamine, thyroxine and pharmaceutical antidepressants.

Valerian

HISTORICAL NOTE The sedative effects of valerian have been recognised for over 2000 years, having been used by Hippocrates and Dioscorides in ancient Greece. Over the past 500 years, valerian was widely used in Europe as a calmative for nervousness or hysteria and also to treat dyspepsia and flatulence. Legend has it that the Pied Piper put valerian in his pockets to attract the rats out of Hannover. Valerian was widely used by the Eclectic physicians and listed in the United States Formulary until 1946.

COMMON NAME
Valerian

OTHER NAMES
All-heal, amantilla, balderbrackenwurzel, baldrian, baldrianwurzel, fragrant valerian, heliotrope, herbe aux chats, katzenwurzel, phu germanicum, phu parvum, valeriana, wild valerian

BOTANICAL NAME/FAMILY
Valeriana officinalis (family Valerianaceae)

PLANT PART USED
Rhizome

CHEMICAL COMPONENTS
Valtrates, didrovaltrates, isovaltrates, monoterpenes, sesquiterpenes, caffeic, gamma-amino butyric and chlorogenic acids, beta-sitosterol, methyl 2-pyrrolketone, choline, tannins, gum, alkaloids, a resin. Essential oils (0.5–2%) in the plant contain the compounds bornyl acetate and the sesquiterpene derivatives valerenic acid, valeranone and valerenal.

The chemical composition of valerian varies greatly depending on such factors as plant age and growing conditions. Processing and storage of the herb also affects its constituents, such as the iridoid esters, which are chemically unstable.

MAIN ACTIONS

Anxiolytic and hypnotic
Extensive pharmacological research has been conducted; however, identifying the main active constituents in valerian and their mode of action remains unclear and several neurobiological mechanisms are believed to be at work. In vitro tests so far have demonstrated that valerian stimulates the release of GABA, inhibits GABA reuptake and may have an effect at GABA receptors (Ortiz et al 1999, Santos et al 1994). There is also evidence of agonist effects at the human A_1 adenosine receptor for the methanolic extract (Schumacher et al 2002).

A recent study using a rat model identified anxiolytic and antidepressant activity for an ethanolic extract of valerian (phytofin Valerian 368) (Hattesohl et al 2008).

Both in vivo and numerous clinical studies confirm sedative or hypnotic activity (Ammer & Melnizky 1999, Balderer & Borbely 1985, Della Loggia et al 1981, Donath et al 2000, Dorn 2000, Leathwood & Chauffard 1985, Gerhard et al 1996, Gessner & Klasser 1984, Leuschner et al 1993, Lindahl & Lindwall 1989, Schulz et al 1994, Wheatley 2001).

Antispasmodic
Both in vitro and in vivo studies provide evidence of antispasmodic activity on smooth muscle (Hazelhoff et al 1982).

OTHER ACTIONS
A pharmacokinetic study with healthy adults found that typical doses of valerian are unlikely to produce clinically significant effects on the CYP2D6 or CYP3A4 pathways of metabolism (Donovan et al 2004). These results were confirmed in another human pharmacokinetic study that found no evidence that valerian affects CYP3A4/5, CYP1A2, CYP2E1 and CYP2D6 activity (Gurley et al 2005).

CLINICAL USE
In practice, valerian is rarely used as a stand-alone treatment and is often combined with other sedative or relaxant herbs, such as chamomile, passionflower, skullcap, lemon balm and hops.

Insomnia
Numerous RCTs have investigated the effects of different valerian preparations as a treatment for insomnia. Some studies have involved people with confirmed sleep disturbances and others involved healthy subjects with no sleep problems. Treatment time-frames varied from acute (1 dose) to longer term (over 1 month) and doses have varied considerably. Some studies use only subjective data such as self-reported sleep quality whereas others use objective measures such as polysomnographs. As a result, interpreting the evidence is difficult and no clear picture strongly emerges. Overall, it appears that some preparations have benefits for poor sleepers and valerian may be better suited to reducing sleep latency rather than other disturbances, but this is not yet a definitive conclusion. Findings from a pharmacokinetic study however lend support to this conclusion, as it demonstrated that valerenic acid (a pharmacologically active marker compound for valerian) was increased in serum within an hour after ingestion, reached maximal levels between 1 and 2 hours then fell, with no detectable levels observed after 4 hours (Anderson et al 2005). This pharmacokinetic pattern is also consistent with the finding that valerian does not produce residual morning sedation.

A number of different valerian products have been studied in clinical trials (e.g. Baldosedron, Baldrien-Dispert, Euvegal, Harmonicum Much, Seda-Kneipp, Sedonium, Valdispert, Valverde and Valerina Nutt). The LI 156 valerian extract is one of the most studied.

A systematic review by Stevinson and Ernst (2000) identified 19 studies involving valerian treatment that were published prior to May 1999. Of these, nine were chosen for inclusion because they were randomised, measured sleep parameters and tested single ingredient valerian products. Three studies considered the cumulative effects of long-term use of valerian whereas six investigated the effects of single-dose treatment. Two of the three studies investigating repeated administration of valerian found that effects were established by 2 weeks. The most rigorous placebo-controlled study showed that valerian LI 156 (600 mg) produced improvement on nearly all measures between weeks 2 and 4 (Vorbach et al 1996 as reported by Stevinson & Ernst 2000). The 4-week study involved 121 volunteers and assessed clinical effectiveness using four validated rating scales. At the end of the study, valerian was rated better than placebo on the Clinical Global Impression Scale, and at study conclusion (day 28) 66% of patients rated

valerian effective, compared to 26% with placebo. Of the six studies investigating acute effects, valerian produced positive results in three whereas in the other three it was no better than placebo.

Interpretation of study results is difficult because of varying research methodologies. For example, some studies used surveys whereas others used EEG readings, some were conducted at home and others in hospitals or sleep laboratories, and pre-bedtime variables (e.g. caffeine consumption) were not fully controlled. Additionally, some studies used healthy volunteers with no sleep disturbances with little scope to observe further improvements. Since then, several other studies have been published.

In 2007, a comprehensive systematic review conducted by Taibi et al identified 37 separate studies of which 29 were controlled trials which evaluated valerian for both efficacy and safety, and eight were open-label trials which evaluated for safety only (Taibi et al 2007). The search was not limited to English language publications, thereby identifying many additional studies published by European research groups, including 17 studies published in German. The review evaluated data from RCTs and trials of other designs which investigated ethanolic extracts of valerian, aqueous extracts of valerian and valerian herbal combination treatments in people with sleep disturbances and in those who were considered healthy.

Six randomised, double-blind studies of an ethanolic extract of valerian (mainly LI 156 Sedonium®) at a dosage between 300 and 600 mg before bedtime were assessed (Taibi et al 2007). Two studies measured polysomnographic outcomes and 4 collected only subjective measures of sleep quality. Overall, the ethanolic extract was not found to significantly affect objective or subjective sleep outcomes compared to placebo, however it did improve subjective sleep quality ratings in a manner similar to benzodiazepines. If we assume benzodiazepines perform better than placebo, then this is a positive outcome.

Seven studies evaluated the effects of aqueous preparations of valerian (Valdispert® Dixa SA Switzerland) at doses ranging from 400 mg/night to 450 mg three times daily (Taibi et al 2007). Four studies involved healthy subjects, 2 were of elderly people with sleep disturbances and one study was of people with difficulties in sleep onset. Once again, methodologies were highly varied. Only one study excluded volunteers with medical conditions that could contribute to poor sleep. As may be expected with such variations, results were mixed. The two studies involving elderly volunteers produced contradictory results whereas reduced subjective latency was demonstrated in people with sleep onset disturbances. Healthy volunteers appeared to gain no benefit from the treatment.

Five further studies used valerian extracts which were standardised to valepotriate content (Taibi et al 2007). Three of these studies used *V. edulis* (one used Harmonicum Much®) as a source of valepotriates and one used *V. wallichii* (Valmane®). The dose of valepotriates varied from 60 to 120 mg and one preparation of *V. officinalis* used a preparation standardised to 450 mg of valerenic acid (Mediherb, QLD Australia). Whilst methodologies varied considerably, overall standardised extracts appeared to reduce sleep disturbances when compared to placebo. A dose of 100 mg valepotriates taken three times a day was found to significantly improve sleep quality ratings in people withdrawing from benzodiazepines when compared to placebo. Additionally, 60 to 120 mg valepotriates was similarly effective in people who had reported disturbed sleep.

Valerian herbal combinations featured in 10 studies overall, valerian–lemon balm in 4 and valerian–hops in 6 (Taibi et al 2007). The studies using valerian–lemon balm combinations were shown to reduce sleep latency and increase sleep quality in people suffering sleep disturbances whereas no change was observed in healthy subjects. In contrast, studies with valerian–hops combinations found no significant improvements using polysomnographic equipment or subjective sleep outcomes (Taibi et al 2007). The hops–valerian treatments used were ZE 91019 (Alluna®) or another product Hova® (extraction unknown).

In 2007, a later randomised placebo controlled study was published which compared a valerian–hops combination (Ze 91019) to valerian monotherapy (Ze 911) (Koetter et al 2007). The herbal combination treatment contained the same amount of valerian (500 mg) as monotherapy, thereby allowing researchers to evaluate what contribution hops (120 mg) would make to the outcomes measured. Volunteers suffering from non-organic insomnia were given either treatment or placebo for 4 weeks. In contrast to previous studies cited by Taibi et al, the valerian–hops combination was significantly superior to placebo in reducing sleep latency, improving clinical global impression scores and increasing slow-wave sleep, whilst the single valerian extract failed to show benefits beyond placebo.

Comparisons with benzodiazepines

Three randomised studies have compared valerian monotherapy with benzodiazepine drugs. One double-blind trial found that subjects treated with either 600 mg valerian (ethanolic extract) or 10 mg oxazepam experienced significantly improved sleep, with no statistically significant differences detected between the treatments (Dorn 2000). Another study comparing the immediate sedative effects and residual effects of a valerian and hops preparation, a sole valerian preparation, flunitrazepam and placebo found that subjective perceptions of sleep quality were improved in all treatment groups; however, only flunitrazepam treatment impaired performance the morning after, as assessed both objectively and subjectively (Gerhard et al 1996). Furthermore, 50% of subjects receiving flunitrazepam reported mild side-effects compared with only 10% from the other groups.

A 2002 double-blind randomised trial compared the effects of valerian extract LI 156 (Sedonium) 600 mg/day to 10 mg oxazepam over 6 weeks in 202 patients with non-organic insomnia (Ziegler et al 2002). The multicentre trial took place at 24 study centres in Germany and found that valerian

treatment was at least as efficacious as oxazepam, with both treatments improving sleep quality. Subjectively, 83% of patients receiving valerian rated it as 'very good' compared with 73% receiving oxazepam.

Children

The efficacy and tolerability of a valerian and lemon balm combination (Euvegal® forte) was tested in a large, open, multicentre study of 918 children (aged under 12 years) with restlessness and nervous sleep disturbance (dyssomnia) (Muller & Klement 2006). Both investigators' and parents' ratings revealed a reduction in the severity of symptoms for most patients. The study reported that 81% of children with dyssomnia experienced an improvement and 70% of children with restlessness improved. Treatment was generally rated as good or very good and considered well tolerated. Each Euvegal® forte tablet consisted of 160 mg valerian root dry extract (*Valeriana officinalis* L.) with a drug-extract ratio of 4–5:1 (extraction solvent ethanol 62% v/v) and 80 mg lemon balm leaf dry extract (*Melissa officinalis*) with a drug-extract ratio of 4–6:1 (extraction solvent ethanol 30% v/v). The standard dosage of Euvegal® forte (4 tablets daily) was used by 75% of patients and chosen by the investigator.

Anxiety and psychological stress states

Less investigation has taken place to determine the role of valerian as a treatment for anxiety states.

A randomised study found that low-dose valerian (100 mg) reduced situational anxiety without causing sedation (Kohnen & Oswald 1988). Positive results were also obtained in a smaller open study of 24 patients suffering from stress-induced insomnia who found treatment (valerian 600 mg/day for 6 weeks) significantly reduced symptoms of stress and insomnia (Wheatley 2001). Another randomised trial compared the effects of a preparation of valepotriates (mean daily dose 81.3 mg) with diazepam (mean daily dose 6.5 mg) and placebo in 36 outpatients with GAD under double-blind conditions (Andreatini et al 2002). After 4 weeks' treatment, all groups had significant reductions in Hamilton anxiety (HAM-A) scale scores; however, only those receiving valepotriates or diazepam showed a significant reduction in the psychic factor of HAM-A.

Kava kava is a herbal medicine also used in the treatment of anxiety and found to be effective in clinical studies (Pittler & Ernst 2002). A study that compared the effects of kava kava to valerian and placebo in a standardised mental stress test found that both herbal treatments reduced systolic blood pressure, prevented a stress-induced rise in heart rate and decreased self-reported feelings of stress (Cropley et al 2002).

A 2006 Cochrane review concluded there is insufficient evidence to draw any conclusions about the efficacy or safety of valerian compared with placebo or diazepam for anxiety disorders (Miyasaka et al 2006). RCTs involving larger samples and comparing valerian with placebo or other interventions used to treat of anxiety disorders, such as antidepressants, are needed.

Muscle spasm and cramping

Valerian preparations have long been used to treat a wide variety of gastrointestinal disorders associated with spasms such as diarrhoea, colic and irritable bowel. It has also been used to relieve cramping in dysmenorrhoea. Although no controlled studies are available to confirm clinical effectiveness in these conditions, valerian is likely to exert some degree of antispasmodic activity based on its pharmacological actions.

OTHER USES

Fibromyalgia

One randomised study, which was investigator blinded, tested the effects of whirl baths with plain water or with water containing pine oil or valerian on pain, disturbed sleep and tender point count in 30 outpatients with generalised fibromyalgia. Valerian significantly improved wellbeing and sleep together with decreasing tender point count, whereas baths with pine oil worsened pain and plain water baths reduced pain but had no effect on wellbeing and sleeplessness (Ammer & Melnizky 1999).

Benzodiazepine withdrawal

Although no clinical studies are available, the herb is also used in practice to reduce dependency on benzodiazepine drugs. Valerian is prescribed together with other herbal medicines and psychological counselling while the benzodiazepine dose is slowly reduced.

DOSAGE RANGE

- Infusion of dried root: 3–9 g/day.
- Liquid extract (1:2): 2–6 mL/day.
- Tincture (1:5): 5–15 mL/day.
- When used for insomnia, valerian should be taken approximately 1 hour prior to bedtime.

According to clinical studies

- Anxiety: 100 mg–600 mg/day of the dried root or valepotriates (mean daily dose 81.3 mg).
- Insomnia: doses above 600 mg/day of dried root taken 1 hour before bedtime. Ethanolic extract of valerian: 300–600 mg before bedtime. Aqueous preparations of valerian: 400 mg/night to 450 mg three times daily. Standardised extracts: 60–120 mg valepotriates or 450 mg of valerenic acid before bedtime.
- For benzodiazepine withdrawal: 100 mg valepotriates taken three times daily

TOXICITY

According to one case report, a dose of valerian taken at approximately 20-fold the recommended therapeutic dose appears to be benign (Willey et al 1995).

ADVERSE REACTIONS

As with numerous pharmaceutical sedatives, next morning somnolence is a possible side-effect of therapy; however, evidence from two human studies suggests this is not associated with valerian use (Gerhard et al 1996, Kuhlmann et al 1999).

Additionally, evidence from a pharmacokinetic study indicates this is highly unlikely.

Vivid dreams were reported in one study; however, this is considered rare by clinicians (Wheatley 2001).

Paradoxical effects have been observed in clinical practice; however, this also appears to be rare (Mills & Bone 2000).

Occasionally, headache and gastrointestinal symptoms have been reported (Ernst 2001).

SIGNIFICANT INTERACTIONS

Pharmaceutical sedatives

Theoretically, potentiation effects may occur at high doses; however, this has not been tested under clinical conditions — observe patients taking valerian concurrently with pharmaceutical sedatives.

Alcohol

RCTs have shown no potentiation effects with alcohol use (Ernst 2001).

CONTRAINDICATIONS AND PRECAUTIONS

No known contraindications. Care should be taken when driving a car or operating heavy machinery when high doses are used.

PREGNANCY USE

No restrictions are known; however, safety has not been well established in pregnancy. No significant negative effects have been reported in toxicological tests with animals and none reported in clinical studies (Upton 1999).

PATIENTS' FAQs

What will this herb do for me?

Valerian is classified as a mild, sedative herbal medicine. It can reduce the time it takes to fall asleep at night and may also relieve stress and anxiety during the day. When added to a bath, it may increase relaxation, wellbeing and reduce some forms of pain.

When will it start to work?

For some, it works within an hour of the first dose; however, research suggests it works best after several weeks of regular use.

Are there any safety issues?

From the available evidence, next-day drowsiness is uncommon and physical addiction highly unlikely. Taking high doses during the day may increase drowsiness, so care is needed when driving a car or operating heavy machinery.

PRACTICE POINTS/PATIENT COUNSELLING

- There is good scientific evidence to support the use of valerian as a treatment for insomnia; however, it appears that ongoing use may be more effective than single-dose use and effects on sleep progress over several weeks.
- It appears to be best suited to reducing sleep latency (i.e. time taken until falling asleep) and improves subjective assessments of sleep.
- There is no evidence of next-day somnolence or significant adverse effects.
- Valerian also relieves symptoms of stress and anxiety, with several studies observing effects similar to benzodiazepines; however, further research is required.
- Due to its pungent odour, solid-dose forms may be preferable.

Vitamin A

HISTORICAL NOTE In ancient Egypt and Greece, physicians recommended the liver of an ox to cure night blindness. Although this could be interpreted as applying the liver locally, it could also refer to ingesting some, which would have provided a good source of vitamin A and proven to be a cure for night blindness caused by deficiency (Shils et al 2006). Modern day scientific research into vitamin A began in 1913, with its discovery at both Yale and Wisconsin Universities. Researchers at both sites independently noticed that the substance could promote survival and growth of young animals. Since then, each decade has brought important new discoveries about vitamin A. The period from the 1960s to 1980s was particularly fruitful, as several proteins essential for transport and metabolism of vitamin A were isolated and purified. During the 1980s, another major discovery was made when a link between childhood mortality and subclinical deficiency was identified. Vitamin A research continues to interest a wide spectrum of researchers and influence public health initiatives.

BACKGROUND AND RELEVANT PHARMACOKINETICS

The term 'vitamin A' refers to a family of fat-soluble dietary compounds that are structurally related to retinol, and share its biological function. Vitamin A is found in foods as itself or as a precursor, which is converted into vitamin A in the body. The precursors, known as carotenes, are found in deep yellow, green and red coloured plants.

Retinyl esters, retinol or carotenoids from the diet, or supplements, are hydrolysed in the small intestine where they are absorbed as retinol into the mucosal cells (Miller et al 1998). Entering the body within the lipid core of chylomicrons, they are transported through lymph to blood, where it then recycles between plasma and tissues numerous times, before arriving at the liver. The liver performs three key tasks in relation to vitamin A. It is responsible for regulating the secretion of retinol to specific transport proteins known as 'retinol-binding proteins', it serves as a major storage organ and is the major site of vitamin A catabolism. Vitamin A metabolites are excreted mainly through the faeces and urine.

The body has a good capacity for vitamin A storage; however, its ability to rapidly dispose of excess vitamin A is quite limited (Shils et al 2006). This may explain why vitamin A can accumulate to toxic levels when intake greatly exceeds requirements.

This monograph will focus on preformed vitamin A and retinoic acid only. Further information about the carotenoids can be found in other monographs.

FOOD SOURCES

Preformed vitamin A (retinyl esters) is chiefly found in foods of animal origin, such as liver, red meat and eggs, as well as in fish, milk, butter and cream.

Cooking can destroy up to 40% of the vitamin A content of food (Wahlqvist et al 1997).

DEFICIENCY SIGNS AND SYMPTOMS

- Night blindness, which can progress to complete blindness if left untreated.
- Keratinisation of epithelial surfaces, causing them to dry and harden.
- Poor dental health.
- Compromised immune function.
- Reduced reproductive capabilities.

Primary deficiency

Primary deficiency is caused by prolonged dietary deprivation. In large areas of the world, vitamin A deficiency is endemic, causing widespread blindness and mortality (Sklan 1987).

Secondary deficiency

Secondary deficiency can develop when absorption, storage or transport is reduced or carotene is not adequately converted to vitamin A. Conditions associated with risk of secondary deficiency

include malabsorption syndromes, such as coeliac disease and cystic fibrosis (CF), pancreatic disease, duodenal bypass, congenital partial obstruction of the jejunum, obstruction of the bile ducts, giardiasis, diabetes and kwashiorkor.

MAIN ACTIONS

Vitamin A is an essential nutrient required for life and serves two very different biological functions. First, in the form of retinaldehyde, it constitutes the light-sensitive component of the retina, rhodopsin, and second, in the form of retinoic acid, it activates a large number of transcription factors (McCaffery & Drager 1993).

Antioxidant

Vitamin A exhibits free radical scavenging properties.

Growth and development

Vitamin A is essential for embryonic growth. Deficiency, as well as excess, has been shown to be teratogenic in animal studies, suggesting the same may be true in humans. It is currently unclear whether vitamin A itself or one of its metabolites or both are responsible for the teratogenic effects seen with high exposure (Miller et al 1998).

Vitamin A is also necessary for healthy bone formation in children.

Immune function and maintenance of epithelial surfaces

Vitamin A maintains the health of epithelial cells in the body, which form an important barrier to infection, and the function of the immune system. More specifically, studies in animal models and cell lines show that vitamin A and related retinoids play a major role in immunity, including expression of mucins and keratins, lymphopoiesis, production of antibodies, and the function of neutrophils, natural killer (NK) cells, macrophages, T-lymphocytes and B-lymphocytes (Semba 1999). It has also been shown to potentiate antibody responses and lymphocyte proliferation in response to antigens and restore the integrity and function of mucosal surfaces (Semba 1994).

Vision

Vitamin A is involved in ocular health and function in two distinct ways. First, in the form retinaldehyde, it is an essential component of rhodopsin and is necessary for maintaining vision (Wahlqvist et al 1997). Deficiency states initially cause a reversible night blindness that can progress to complete blindness due to photoreceptor degeneration (McCaffery & Drager 1993). Second, as retinoic acid, it maintains normal differentiation of cells in the conjunctiva, cornea and other ocular structures, with deficiency resulting in xerophthalmia (dry eye) and corneal ulceration. In xerophthalmia, the cells lining the cornea lose their ability to produce mucus, and therefore lubrication of the eye becomes compromised. Dirt particles that eventually enter the eye are more easily able to scratch the surface, increasing the risk of infection and, ultimately, blindness.

Chemoprevention

Studies in cell culture and animal models have documented the capacity for natural and synthetic retinoids to reduce carcinogenesis significantly in skin, breast, liver, colon, cervical, prostate and other sites (Ross 1999). The mechanism of action responsible has not been fully elucidated, but several theories exist. It has been known since early in the 20th century that vitamin A deficiency can induce metaplastic changes to epithelial cells (De Luca et al 1997). Retinoic acid is thought to act as an inhibitor of carcinogenesis by interfering with promotion rather than with initiation, which may be blocked by inhibition of proliferation, stimulation of differentiation or induction of apoptosis (Niles 2000). Other research suggests it may also inhibit the final stage when malignant conversion of a benign tumour to a carcinoma occurs (De Luca et al 1997).

CLINICAL USE

Deficiency: prevention and treatment

Traditionally, vitamin A supplementation has been used to treat deficiency or prevent deficiency in conditions associated with risk of vitamin A deficiency, such as diabetes, hyperthyroidism, protein deficiency, intestinal infections and infestations and CF.

Paediatrics

Reducing infection severity

Vitamin A deficiency impairs systemic immunity and increases the incidence and severity of infections during childhood, particularly measles and infectious diarrhoea. There is also evidence that infectious diseases, such as measles, will in turn depress serum retinol concentrations, by >30%, according to one study (Enwonwu & Phillips 2004). This phenomenon does not just occur in undernourished populations. A study of well-nourished children in the USA with measles identified that 50% had concurrent vitamin A deficiency (Arrieta et al 1992).

It is suspected that infectious diseases influence retinol metabolism through mechanisms that are more complex than simple loss of retinol stores (Enwonwu & Phillips 2004). Impaired synthesis of retinol-binding protein and transthyretin and decreased expression of the receptors for retinoic acid could also be responsible. As such, the use of vitamin A in the treatment of infectious disease is not limited to developing countries, but may also have application in well-nourished populations.

In areas where vitamin A deficiency may be present, the World Health Organization (WHO) recommends administration of an oral dose of 200,000 IU (or 100,000 IU in infants) of vitamin A per day for 2 days to children with measles (D'Souza & D'Souza 2002a, 2002b). It has also been recommended that prophylactic vitamin A supplements be given to all infants and young children (0–59 months), pregnant women and post-partum women, 6 weeks after delivery, in these same areas (Ross 2002).

According to a 2005 Cochrane review, the WHO recommendation of two large doses of

vitamin A does successfully lower the risk of death from measles in hospitalised children under the age of 2 years, but not in all children with measles (Huiming et al 2005).

Reducing secondary infections associated with measles

A meta-analysis of six clinical trials found a 47% reduction in the incidence of croup in children with measles who were treated with 200,000 IU of vitamin A on 2 consecutive days. One study in the analysis reported a 74% reduction in the incidence of otitis media, but this was not confirmed in others. A statistically significant decrease in the duration of diarrhoea, pneumonia, hospital stay and fever was also observed (D'Souza & D'Souza 2002a).

Reducing childhood mortality

It has been estimated that a 23% reduction in young child mortality is possible with improvements in vitamin A status. This is most marked for deaths due to acute gastroenteritis and measles, but not acute respiratory infections or malaria (Ramakrishnan & Martorell 1998) and is particularly the case for older preschool children, whereas the effect on infants is less clear. In areas of endemic vitamin A deficiency, vitamin A supplementation was not found to lower the incidence of illness such as diarrhoea, dysentery or fever; however, it did reduce mortality with fewer case fatalities in young children with these diseases compared to placebo (Tielsch et al 2007). In newborn infants supplemented with 50,000 IU of vitamin A, all-cause mortality at 6 months was reduced by 15% (Klemm et al 2008).

Reducing febrile neutropenia

In a cohort of 49 children with cancer, those with plasma retinol levels below20 microgram/dL at diagnosis had a greater risk of developing episodes of febrile neutropenia compared to children with higher vitamin A status (Wessels et al 2008).

Very low birth weight (VLBW) infants

Supplementing VLBW infants with intramuscularly administered vitamin A is associated with a reduction in death or oxygen requirement at 1 month of age (Darlow & Graham 2007).

Reducing the risk of HIV transmission from mother to infant

The dominant mode of acquisition of HIV infection for children is mother-to-child transmission. Currently, this results in more than 2000 new paediatric HIV infections each day worldwide. A 2005 Cochrane review analysed results from four trials, which enrolled 3033 HIV-infected pregnant women, and found no evidence to support the use of vitamin A supplementation for this indication (Wiysonge et al 2005). One benefit that was identified for vitamin A supplementation was an improvement in infant birth weight. Neither maternal nor neonatal vitamin A supplementation significantly affected the overall mortality of children exposed to HIV by 2 years of age. Interestingly in infants who were HIV-negative at baseline but positive by 6 weeks of age, supplementation reduced mortality by 28%, whereas in infants who did not become HIV-positive by 6 weeks, supplementation doubled the risk of mortality by age 2 years. It has been suggested that vitamin A supplementation may have increased viral load among babies who subsequently became infected during breastfeeding, but this remains untested (Humphrey et al 2006b).

Fetal growth

Low levels of vitamin A impair fetal growth. In a cross-sectional study on 100 neonate–mother pairs, lower placental and neonatal levels of vitamin A were associated with prematurity and intrauterine growth retardation (Agarwal et al 2008).

Cancer prevention

Most forms of cancer arise from cells that are influenced by vitamin A (Wardlaw et al 1997). Combined with its antioxidant and immunomodulatory activities, vitamin A has been considered as a potential chemopreventive agent. Research thus far using cell cultures and animal models has identified the ability for natural and synthetic retinoids to reduce carcinogenesis significantly in skin, breast, liver, colon, prostate and other sites (Krinsky 2002). A look at the literature shows that impressive treatment results have mainly been obtained for synthetic retinoids and the relationship between natural vitamin A ingestion and cancer is less clear in humans.

In a cohort study of 3254 Japanese subjects aged from 39 to 85 years, high-serum levels of carotenoids were associated with reduced mortality rates of cancer of all sites or of cardiovascular disease, while high-serum levels of beta-carotene, total carotene, provitamin A and total carotenoids reduced risk of colorectal cancer or stroke at follow-up after 11.7 years. Serum retinol and tocopherols, however, were not associated with a reduction in risk of mortality from cancer or cardiovascular disease (Ito et al 2006).

Prostate cancer

A cohort study of 1985 men previously exposed to asbestos found whilst increasing intakes of vitamin C-rich vegetables such as peppers and broccoli were associated with reduced risk of prostate cancer, vitamin A intake (supplement of 7.5 mg retinol daily) did not lower risk (Ambrosini et al 2008). Similarly, in a large prospective study within the European Prospective Investigation into Cancer and Nutrition (EPIC) study, no associations were found between the plasma concentrations of carotenoids, retinol or tocopherols and overall prostate cancer risk (Key et al 2007).

Gastric cancer

In a large nested case–control study of patients with gastric cancer, a higher plasma concentration of beta-cryptoxanthin, zeaxanthin, retinol and alpha-tocopherol was associated with a significantly lower risk of developing gastric cancer (Jenab et al 2006). A high intake of vitamin A, alpha-carotene and beta-carotene was associated with a reduced

risk of gastric cancer in a prospective cohort study of 82,002 Swedish adults. However, no protective effect was found from beta-cryptoxanthin, lutein and zeaxanthin or lycopene intake (Larsson et al 2007). In contrast, a study among 36,745 Japanese subjects (aged 40–69) with *Helicobacter pylori* infection did not find a statistically significant association between plasma levels of retinol or lutein/zeaxanthin, lycopene, alpha- or gamma-tocopherol and the risk of gastric cancer (Persson et al 2008).

Lung cancer

A number of epidemiological studies have identified an inverse association between risk of lung cancer and serum carotenoid levels, but intervention studies have produced conflicting results. In general, vitamin A is supplied together with carotenoids making it difficult to determine the role of vitamin A as a stand-alone agent. (See Beta-carotene monograph for further discussion.) The pooled analysis of the primary data from eight prospective studies involving 430,281 subjects found those with the highest quintile of intake of vitamins A, C and E and folate from food-only had a statistically significant 28% reduction in the risk of lung cancer compared to those in the lowest quintile. This protective effect was lost, however, after adjusting for multiple risk factors for lung cancer, including smoking habits (Cho et al 2006). In a case-controlled study involving 333 patients diagnosed with primary lung cancer, however, a significantly lower risk of lung cancer was associated with a higher intake of vitamin A, alpha-carotene and beta-carotene rich food. Interestingly, no protective effect was observed for vitamin A consumed as supplements (Jin et al 2007). In patients exposed to blue asbestos, low plasma retinol levels were associated with increased risk of developing mesothelioma and lung cancer (Alfonso et al 2006). Patients with lung cancer have been found to have similar levels of retinol but lower levels of serum metabolites retinyl palmitate and retinoic acid levels compared to healthy controls, suggesting retinol metabolism may be impaired in these patients (Moulas et al 2006).

Other cancers

In a prospective cohort study involving 89,835 women aged between 40 and 59 years, dietary intake of carotenoids or vitamins A, C or E was not found to be associated with a reduced risk of ovarian cancer (Silvera et al 2006). While a prospective study of 88,759 women and 47,828 men found the intake of vitamins A and C from food was inversely associated with the risk of renal cell cancer in men, the total retinol intake from sources such as supplements, liver, vitamin A–fortified milk and cereals was not associated with a reduction in risk. The beneficial effects may possibly be due to other protective nutrients or chemicals in carotenoid-containing foods (Lee et al 2006).

Adjunct in chemotherapy

Vitamin A (350,000–500,000 IU/day) was randomly allocated to patients in a group of 100 with metastatic breast carcinoma treated by chemotherapy (Israel et al 1985). Patients supplemented with vitamin A showed a greater than two-fold increase in the complete response compared to controls (38% versus 15%; $P < 0.02$). Among chemotherapy responders in both groups, the projected 43-month survival rate was 93% in vitamin A-supplemented responders versus 30% in non-supplemented responders ($P < 0.02$).

Infections

Urinary tract

A placebo-controlled, double-blinded study involving 24 patients found a single dose of 200,000 IU vitamin A in addition to antimicrobial therapy significantly reduced recurrent urinary tract infections. In the treatment group, the rate of infection reduced to 0.12 attacks/month in the first 6-month period, and 0.29 attacks/month in the second 6-month period, compared to 0.47 attacks/month and 0.44 attacks/month respectively in the control group (Yilmaz et al 2007).

Lower respiratory tract

A recent Cochrane systematic review of nine randomised controlled trials (RCTs) involving 33,179 children examined the effectiveness and safety of vitamin A in preventing acute lower respiratory tract infections (LRTIs) in children up to 7 years old. Six studies used mega-dose vitamin A (100,000–206,000 IU) (every 4 months for a year or as once off), whilst four studies used low-dose (5000 IU daily, 10,000 IU weekly, 8333 IU weekly, and 20,000 IU or 45,000 IU every 2 months). Most studies did not find a beneficial effect on LRTI. Whilst two studies found vitamin A supplementation prevented acute LRTIs in children with low serum retinol or those with a poor nutritional status, unexpectedly three studies found vitamin A was associated with negative outcomes including an increased incidence of acute LRTI, and increased symptoms of cough, fever and rapid breathing. The authors concluded that the effect of vitamin A was influenced by the child's nutritional status or weight, with supplementation increasing the acute LRTI episodes in 'normal' children (Chen et al 2008).

HIV

The Zimbabwe Vitamin A for Mothers and Babies (ZVITAMBO) project examined the effects of a vitamin A supplementation on serum retinol concentration, and mortality and morbidity among HIV-positive and HIV-negative post-partum women. A single 400,000 IU dose of vitamin A given during the immediate post-partum period had no effect on maternal mortality of both HIV-negative and positive women after 2 years compared to placebo. Among HIV-positive women, the supplementation reduced clinic visits for treatment for malaria, cracked and bleeding nipples, pelvic inflammatory disease and vaginal infection, but did not lower overall rates of hospitalisation. Whilst vitamin A deficiency was more common among HIV-positive women, serum levels of retinol were unresponsive to supplementation except

in those with a CD4 count of less than 200 cells × 10^6/L (Zvandasara et al 2006). In a subsample of HIV-negative women enrolled in ZVITAMBO trial, a single dose of 400,000 IU vitamin A within 96-h post-partum did not reduce the incidence of HIV infection; however, HIV-negative women with low vitamin A levels (serum retinol < 0.7 micromol/L) were 10.4 times more likely to acquire HIV. In women with a low vitamin A who received supplementation, there was a slightly (non-significantly) lower incidence of HIV (Humphrey et al 2006a).

Dermatology

Numerous clinical studies have shown beneficial effects of vitamin A or its derivatives on skin diseases such as acne, psoriasis, ichthyoses, keratodermas, skin cancers, lichen planus and UV-induced skin damage and photo-ageing (Futoryan & Gilchrest 1994). Currently, most research has been conducted with synthetic retinoid derivatives and is not representative of the effects of natural vitamin A. In a study of 100 newly diagnosed, untreated acne patients (mean age 21 years), plasma levels of both vitamin A and vitamin E were found to be significantly lower compared to age-matched healthy controls. An inverse relationship was also found between plasma vitamin A concentrations and the severity of the acne (El-Akawi et al 2006).

Topical vitamin A improves the appearance of older skin, and may also increase its resistance to injury and ability to heal. A lotion containing 0.4% retinol was tested in a 6-month randomised controlled trial involving 36 elderly subjects aged between 80 and 96. The lotion was applied three times a week to left or right upper arm, with a lotion without retinol used on the other arm. The retinol-treated skin had fewer fine wrinkles and reduced roughness compared to the skin treated with the non-retinol lotion. The effects are due to an increase in glycosaminoglycan which helps the skin retain water, and increased collagen production (Kafi et al 2007).

Ophthalmological diseases

Retinitis pigmentosa

One randomised, double-blind trial found that people receiving 15,000 IU/day of vitamin A experienced a slowed rate of retinal function decline (Berson et al 1993). The mechanism responsible is poorly understood, but it is possible that vitamin A transport or the retention capacity of the retina is abnormal in retinitis pigmentosa; or, defects in the pigment epithelium involving vitamin-associated proteins occurs (Sharma & Ehinger 1999).

> ***Clinical note — Retinitis pigmentosa***
> Retinitis pigmentosa describes a group of hereditary retinal dystrophies, characterised by the early onset of night blindness followed by a progressive loss of the visual field. The underlying pathology is a defect that alters the function of the rod photoreceptor cell and subsequent degeneration of these cells (van Soest et al 1999).

Xerophthalmia

Xerophthalmia is responsible for at least half of all cases of measles-associated blindness and is the cause of at least half a million cases of paediatric blindness worldwide (Sommer 1998). This condition is associated with vitamin A deficiency and protein malnutrition.

Reducing morbidity and mortality of pregnant women

Vitamin A supplements have been recommended in pregnancy to improve outcomes, including maternal mortality and morbidity. There is a Cochrane review of five trials involving 23,426 women that investigated the effects of vitamin A supplementation during pregnancy, alone or in combination with other supplements (Van et al 2002). Trials were heterogeneous and difficult to pool; however, two trials from Nepal and Indonesia suggested beneficial effects of vitamin A supplementation. In addition, daily or weekly vitamin A supplementation reduced night blindness in pregnant women living in high-risk areas. Vitamin A during or after pregnancy has not been found to reduce post-partum mortality in HIV-positive women. See discussion under *Infections*.

Leucoplakia

A Cochrane review of treatments for the prevention of malignant transformation of leucoplakia identified five RCTs involving 245 patients which tested vitamin A and retinoids (used topically or as oral treatment), and one study each for beta-carotene and lycopene. Whilst these studies failed to demonstrate prevention of malignant transformation of leucoplakia, they were associated with a small but significant rate of clinical resolution when compared with placebo or absence of treatment. Retinoic acid and lycopene may also result in histological improvement, though results were based on only a small number of patients. Adverse effects were reported in studies using 13-*cis*-retinoic acid (1–2 mg/kg/day), and high-dose vitamin A (300,000 IU per week) (Lodi et al 2006).

Asthma

A study evaluated serum vitamin A concentrations in 26 well-nourished Japanese children with asthma (mean age of 5.5 years) with C-reactive protein (CRP) concentration <0.6 mg/dL, to exclude the acute phase response. Mean serum vitamin A concentrations were significantly lower in asthmatic children compared to controls, and there was also a significant correlation between CRP and serum vitamin A concentrations in children with asthma (Mizuno et al 2006). This observation was also reported in a case–control study involving 96 subjects which found low serum levels of vitamin A (and lycopene) were associated with an increased risk of bronchial asthma (Riccioni et al 2007). Whether low vitamin A status plays a role in chronic inflammatory processes within the lung

or is reduced as a consequence of long-term disease remains to be tested further.

Lung function in cystic fibrosis (CF)

Patients with CF may have impaired absorption of fat-soluble vitamins such as vitamin A. Some studies indicate vitamin A status is associated with respiratory health in patients with CF. Whether supplemental vitamin A has any benefits in CF is still speculative. A Cochrane systematic review did not find any eligible randomised or quasi-randomised controlled trials, and could not provide any firm conclusions on the effects (beneficial or harmful) of supplementation with vitamin A (O'Neil et al 2008). Previously, a small study involving 38 patients with stable CF (mean age of 15.3 years) found a significant correlation between serum vitamin A concentrations and lung function measurements including forced expiratory volume in 1 s, forced vital capacity and peak expiratory flow (Aird et al 2006). Similarly, a retrospective study found CF patients with reduced vitamin A and E levels (even within the normal range) had increased incidence of pulmonary exacerbations (evaluated by a scale of clinical status including symptoms and chest examination findings) (Hakim et al 2007). It is possible the antioxidant activity of vitamin A reduces oxidative damage to lung tissues and in this way provides some protection in CF. Whilst patients with CF and pancreatic insufficiency are at increased risk of deficiency of fat-soluble vitamins including vitamin A, two studies examining vitamin A status in CF patients found CF patients had higher intake and serum retinol levels compared to those without CF (Graham-Maar et al 2006, Maqbool et al 2008). Monitoring may be required to prevent excessive vitamin A supplementation.

Osteoporosis

Whether high-dose vitamin A supplementation increases the risk of osteoporosis remains unclear.

Evidence supporting the association comes from cell studies, animal studies and some but not all human observational studies. Four large, prospective observational studies reported a positive association between vitamin A intake and osteoporosis and fracture rates (Melhus et al 1998, Feskanich et al 2002, Promislow et al 2002, Michaelsson et al 2003). These studies suggested that the amount needed to reduce bone density may be as low as 1500 retinol equivalents (RE), although vitamin A is normally regarded as safe in amounts up to 3000 RE (Penniston & Tanumihardjo 2006). In contrast, numerous studies have failed to find a significant association (Sowers & Wallace 1990, Houtkooper et al 1995, Kawahara et al 2002, Kaptoge et al 2003, Rejnmark et al 2004, Barker et al 2005, Wolf et al 2005). In a study comparing vitamin A intake, serum vitamin A and bone turnover markers in postmenopausal women, no statistical differences were found between those with osteoporosis compared with those without (Penniston et al 2006). The inconsistency in results may be partly due to the difficulty in accurately assessing vitamin A intake and status, as well as the multiple variables influencing bone health (Ribaya-Mercado & Blumberg 2007).

Anaemia

Vitamin A and iron are inter-dependent nutrients, with iron required for the metabolism of vitamin A and maintenance of circulating levels of retinol; and vitamin A required for the mobilisation of iron from its stores for use in haemoglobin synthesis. Some studies have found improving vitamin A status in deficient individuals improves anaemia (Zimmermann et al 2006, Berger et al 2007, Hyder et al 2007). In a double-blind, randomised trial, 81 children (77% with low vitamin A status) received either vitamin A (200,000 IU) or placebo at baseline and again after 5 months. After 10 months, compared to the placebo group, the vitamin A-treated group had increased levels of retinol, increased haemoglobin and mean corpuscular volume and decreased the serum transferrin receptors indicating improved iron-deficient erythropoiesis. Prevalence of anaemia in the treated group decreased from 54% to 38%. Ferritin levels in the vitamin A group were also decreased, suggesting vitamin A increased mobilisation of hepatic iron stores (Zimmermann et al 2006). In a study comparing the impact of vitamin A on the health of children aged 12–59 months in rural Indonesia, it was found that those who had not received their vitamin A treatment in the previous 6 months were significantly more likely to be anaemic, underweight, wasted, and have higher rates of diarrhoea and fever than children who received vitamin A (Berger et al 2007).

Alternatively, some studies found no association between iron deficiency and vitamin A. In a randomised controlled trial in central Africa, 700 pregnant women (2–24 weeks gestation) with haemoglobin <11.0 g/dL were treated with either vitamin A (5000 IU or 10,000 IU) or placebo, plus iron (60 mg elemental iron as ferrous sulfate), folate (0.25 mg), and sulfadoxine/pyrimethamine for antimalarial prophylaxis until delivery. Whilst women in the vitamin A-treated groups were less likely to have depleted vitamin stores at the end of the pregnancy, there were no significant differences in anaemia, severe anaemia and iron status compared with the placebo group. This population was thought to be less vitamin A deficient compared with Asian countries such as Indonesia and Nepal where positive results have previously been found (van den Broek et al 2006). Similarly, a randomised, placebo-controlled trial conducted with mothers and their infants in Zimbabwe observed no effect on haemoglobin or anaemia levels evaluated 8–14 months after supplementation (400,000 for mothers and 50,000 IU for infants) (Miller et al 2006). In a double-blind trial involving HIV-1-infected pregnant women from Tanzania, subjects were randomised to receive daily supplements of 30 mg beta-carotene + 5000 IU preformed vitamin A only; multivitamins (vitamins B, C and E), preformed vitamin A and beta-carotene plus multivitamins, or placebo. All women also received iron and folate supplements during pregnancy. Whilst

haemoglobin concentrations significantly improved in women in the multivitamin group and their children, those in the beta-carotene and vitamin A only group did not significantly differ from placebo (Fawzi et al 2007).

Mortality risk

In a Cochrane systematic review, the effect of antioxidant supplements on mortality in primary or secondary prevention randomised clinical trials was evaluated; vitamin A used as sole treatment or in combination with other antioxidants (15 trials, mean dose of 20,219 IU) had no significant effect on mortality. In fact, after excluding the high-bias risk trials analysis found vitamin A significantly increased mortality in five trials (Bjelakovic et al 2008). This finding requires further investigation to confidently rule out the possible effect of confounders.

OTHER USES

Vitamin A has also been used in the treatment of menorrhagia and premenstrual syndrome (PMS), to prevent glaucoma and cataract, Crohn's disease, sinusitis and rhinitis.

DOSAGE RANGE

- Vitamin A activity is expressed as a unit called microgram RE (Miller et al 1998): 1 microgram RE = 1 microgram all-trans retinol or 6 microgram all-trans beta-carotene or 3.33 international units (IU) of vitamin A or 1 microgram RE is equivalent in activity to 1.78 microgram of retinyl palmitate and 10 IU activity from beta-carotene.

Recent changes to the Therapeutic Goods Act regarding vitamin A require the following statement be included on the labels of vitamin A preparations for internal use:

1. 'The recommended adult daily intake of vitamin A from all sources is 700 microgram RE (2330 IU) for women, and 900 microgram RE (3000 IU) for men.
2. WARNING — when taken in excess of 3000 microgram RE daily, vitamin A may cause birth defects.
3. If you are pregnant, or considering becoming pregnant, do not take vitamin A supplements without consulting your doctor or pharmacist'.

Australian recommended daily intake (RDI) (in micrograms RE)

Children
1–3 years: 300 microgram/day.
4–8 years: 400 microgram/day.
9–13 years: 600 microgram/day.
Girls, 14–18 years: 700 microgram/day.
Boys, 14–18 years: 900 microgram/day.
Adults
Females: 700 microgram/day.
Males: 900 microgram/day.
Upper level of intake: 3000 microgram/day.
Pregnancy
<18 years: 700 microgram/day.
>18 years: 800 microgram/day.
Lactation: 1100 microgram/day.

Clinical note — Vitamin A toxicity in two young children

In 2001, a report of two children admitted to hospital with symptoms of vitamin A toxicity was published in the *Medical Journal of Australia*. One case involved a 2-year-old girl with anorexia, lethargy and leg pain, an erythematous rash over her back and elbows and irritability. All symptoms resolved over 2 weeks following withdrawal of the supplement. The second case involved a child who had previously been prescribed oral etretinate by a dermatologist (for an unspecified period of time), which was ceased 3 months prior to vitamin A supplementation. In both cases, the dose of vitamin A taken was in excess of that provided by standard over the counter (OTC) products (Coghlan & Cranswick 2001).

- Deficiency without corneal changes: 10,000–15,000 IU/day for 1–2 weeks, until clinical improvement is apparent.
- General treatment doses: 10,000–50,000 IU/day have been used short term.

According to clinical studies

- Reducing secondary infection in children with measles: 200,000 IU of vitamin A on 2 consecutive days when vitamin A deficiency may be present.
- Retinitis pigmentosa: 15,000 IU/day.

TOXICITY

Cumulative toxicity is possible when doses greater than 100,000 IU are ingested long term. Acute toxicity is very difficult to induce in adults, as doses above 2,000,000 IU are required (Hendler et al 2001).

Early signs of toxicity include dry rough skin, cracked lips, coarse hair, sparse hair, alopecia of eyebrows, diplopia, dryness of the mucous membranes, desquamation, bone and joint pain, fatigue and malaise, nausea and vomiting and psychological changes mimicking depression and schizophrenia.

Later signs include irritability, increased intracranial pressure and headache, dizziness, liver cirrhosis, fibrosis and cirrhosis, vomiting, haemorrhage and coma (Miller et al 1998).

People with chronic renal disease typically have elevated plasma retinol levels and therefore may be at greater risk of toxicity if supplementation is used.

It is important to note that beta-carotene is not associated with teratogenic effects or vitamin A toxicity and is considered a far safer nutrient.

ADVERSE REACTIONS

In general, doses of vitamin A that do not exceed physiological requirements have no adverse effects.

SIGNIFICANT INTERACTIONS

Chemotherapeutic agents

Adjunctive treatment may improve drug response — consider individual patient characteristics, form and presentation of cancer, drugs used before administration — use only under professional supervision.

Cholestyramine
Reduces vitamin A absorption — increase dietary intake of vitamin A-rich foods or consider supplementation with long-term use.

Colchicine
Colchicine may interfere with vitamin A absorption and homeostasis — co-administer for beneficial interaction.

HMG-CoA reductase inhibitor drugs (statins)
These drugs increase the serum levels of vitamin A, the clinical significance of which is unclear — observe patients taking this combination (Muggeo et al 1995).

Isotretinoin
Toxicity may be increased — avoid this combination.

Minocycline
Long-term vitamin A use with this drug increases the risk of pseudotumour cerebri — use with caution.

Oral contraceptives
Increased vitamin A levels occur in oral contraceptive pill (OCP) users due to longer storage in the liver (Tyrer 1984) — use caution with large doses of retinol.

Orlistat
Reduces vitamin A levels — increase dietary intake of vitamin A-rich foods or consider supplementation with long-term use.

Tetracyclines
Adjunctive use may increase side effects such as headaches, pseudotumour cerebri — avoid.

CONTRAINDICATIONS AND PRECAUTIONS
Doses greater than 10,000 IU/day long term should be used with caution.

People with liver or renal disease, alcoholism or severe osteoporosis should use vitamin A supplements with caution.

PREGNANCY USE
In the USA, sources state that doses up to 10,000 IU/day are safe in pregnancy, but Australian authorities recommend that supplements containing ≥2500 IU of vitamin A per dose must have pregnancy warning statements on their labels.

It is important to note that beta-carotene, found naturally in plants, is not associated with teratogenic effects or vitamin A toxicity.

The teratogenicity of 13-*cis*-retinoic acid, a synthetic derivative of vitamin A available in Australia as Roaccutane, is well established and that substance is contraindicated in pregnancy.

PATIENTS' FAQs
What will this vitamin do for me?
Vitamin A is essential for health and is involved in many different biochemical processes in the body. Some research has suggested that it reduces the incidence and severity of some infectious diseases in children. Vitamin A or its synthetic derivatives have also been used in many skin conditions such as acne, psoriasis, UV-induced skin damage and photo-ageing and the treatment of some cancers.

When will it start to work?
This will depend on the form of vitamin A being used and the indication it is being used to treat.

Are there any safety issues?
Taking high doses of vitamin A long term can cause side effects and is contraindicated in pregnancy.

PRACTICE POINTS/PATIENT COUNSELLING
- Vitamin A is a fat-soluble antioxidant that is chiefly stored in the liver.
- It is involved in maintaining vision, healthy immune function, necessary for growth and development, reproductive capability and healthy epithelial cell function.
- It is used to treat and prevent deficiency states, and there is clinical evidence that supplementation reduces the incidence and severity of infections during childhood, particularly measles and infectious diarrhoea, reduces the incidence of croup and otitis media in children with measles, and may be useful in retinitis pigmentosa.
- Vitamin A deficiency is widespread in some countries, increasing the risk of childhood infectious disease, mortality and deficiency-associated blindness.
- Excessive vitamin A supplementation can induce a toxicity state that can have serious, sometimes irreversible consequences.

Vitamin B_1

HISTORICAL NOTE The Chinese medical book 'Neiching' describes beriberi in 2697 BC, but it was not known for a long time that vitamin B_1 deficiency was responsible. In 1926, two Dutch chemists isolated anti-beriberi factor from rice bran extracts and in the 1930s its structure was determined.

BACKGROUND AND RELEVANT PHARMACOKINETICS

Vitamin B_1 is a water-soluble compound required by all tissues. It is also known as thiamine, anti-beriberi factor, antineuritic factor and its active coenzyme form: thiamine diphosphate. Thiamine's phosphate ester functions as a coenzyme in carbohydrate metabolism and nerve conduction. The free form is found in plasma, but intracellularly it is phosphorylated to one of three forms: thiamine monophosphate (TMP), thiamine diphosphate (TDP) or thiamine triphosphate (TTP), with the majority as TDP, which is the most active form. The ability of thiamine to shift between these different levels of phosphorylation makes it a key nutrient in energy pathways.

There are two sources of thiamine: dietary and a bacterial source whereby it is synthesised by the normal intestinal microflora. Thiamine is absorbed from the small intestine by a saturable rate-limiting transport mechanism. The absorption of thiamine in the gastrointestinal tract can be impaired by the presence of naturally occurring thiaminases that are found in raw fish or polyhydroxyphenols found in certain food and beverages; for example, coffee, tea, blueberries, red cabbage and brussel sprouts (Groff & Gropper 2009).

It is transported by the portal circulation to the liver where it is metabolised, then excreted mainly through the kidneys. Thiamine is found in high concentrations in skeletal muscle, heart, liver, kidneys and brain and its half-life is approximately 15 days (Singleton & Martin 2001).

CHEMICAL COMPONENTS

Thiamine (vitamin B_1) is a water-soluble substance, consisting of thiazole and pyrimidine rings joined by a methylene bridge.

FOOD SOURCES

Brewer's yeast, lean meat and legumes are considered the richest sources of thiamine. Other sources include cereals, grains, pasta, wheat germ, soy milk, seeds and peanuts.

It is possible to lose up to 85% of the thiamine content in meat through cooking and canning, and up to 60% from cooking vegetables (Tanphaichitr 1999). There is also loss through refining of grains and in some countries, the fortification of wheat flour with B vitamins is mandatory to compensate for this loss.

DEFICIENCY SIGNS AND SYMPTOMS

The body only stores a small amount of thiamine and signs of deficiency tend to develop within 15–18 days of restricted intake.

Beriberi is the classic thiamine deficiency state. General early deficiency signs and symptoms include fatigue, weakness, rigidity (due to corresponding increase in lactic acid production), irritability, poor memory, sleep disturbances, chest wall pain, anorexia, abdominal discomfort and constipation.

There are three forms of beriberi: dry, wet and cerebral, also known as Wernicke–Korsakoff syndrome. Dry beriberi is associated with peripheral neurological changes, whereas cerebral beriberi involves alterations to ocular function, cognitive function secondary to bilateral symmetrical brain lesions in the paraventricular grey matter, producing ataxia, which can also be fatal. In addition to neurological changes, wet beriberi is associated with cardiovascular changes characterised by peripheral vasodilation, sodium and water retention, increased cardiac output and myocardial failure, which can advance to become fatal in severe cases. Although

alcoholism is the major cause of Wernicke–Korsakoff syndrome, it has also been reported in several other conditions such as hyperemesis gravidarum, hyperemesis due to gastroplasty, hyperthyroidism and inadequate parenteral nutrition (Bonucchi et al 2008, Gardian et al 1999, Ogershok et al 2002, Seehra et al 1996, Spruill & Kuller 2002, Tan & Ho 2001, Togay-Isikay et al 2001, Toth & Voll 2001). A recent case report of thrombocytopenia in a patient with Wernicke–Korsakoff syndrome, responsive to thiamine repletion, has introduced the possibility that this may constitute an unusual feature of the deficiency picture (Francini-Pesenti et al 2007).

Primary deficiency

Primary deficiency is caused by inadequate dietary intake of thiamine, particularly in people subsisting mainly on highly polished rice (de Montmollin et al 2002) or unfortified grain products. Insufficient intake may also occur in anorexia and in people receiving total parenteral nutrition (TPN) without supplemental thiamine.

Secondary deficiency

Secondary deficiency is caused by an increased requirement, as in hyperthyroidism, pregnancy, lactation, fever, acute infection, increased carbohydrate intake, folate deficiency, malabsorption states, hyperemesis, prolonged diarrhoea, strenuous physical exertion, breastfeeding, adolescent growth and states of impaired utilisation such as severe liver disease, alcoholism, chronic haemodialysis, diabetes (types 1 and 2) and people taking loop diuretics long term. Additionally, pyruvate dehydrogenase deficiency can result in deficiency (Beers & Berkow 2003, Wahlqvist et al 2002, Thornalley et al 2007, Wardlaw et al 1997). Alternatively, latent primary thiamine deficiencies produce overt clinical features when the patient is exposed to thiamine metabolism stressors, such as those listed above, e.g. pregnancy, surgery etc (Al-Nasser et al 2006).

> ***Clinical note — Thiamine deficiency is not uncommon***
>
> Several observational studies have reported that thiamine deficiency is not uncommon in the elderly. A study of 118 elderly hospital patients identified a moderate deficiency incidence of 40% (Pepersack et al 1999). Similar results were obtained in another survey where marginal thiamine deficiency had an incidence of 31% and frank deficiency of 17% (O'Keeffe et al 1994). The importance of including thiamine deficiency in the diagnostic work-ups of at-risk individuals is underscored by the high mortality rate in Wernicke–Korsakoff syndrome (10–20%), reported to be directly the result of under-diagnosis (Bonucchi et al 2008). Similarly, it is important to keep in mind that there is significant inter-individual variability in both susceptibility to thiamine deficiency and its consequences (Al-Nasser et al 2006).
>
> Besides inducing deficiency signs and symptoms, preliminary research suggests that inadequate intake could increase susceptibility to neurodegeneration, particularly in aged organisms (Nixon et al 2006, Pitkin & Savage 2004).

MAIN ACTIONS

Coenzyme

Carbohydrate and branched-chain amino acid metabolism

Thiamine serves as a cofactor for several enzymes involved in carbohydrate catabolism, including pyruvate dehydrogenase, transketolase and alpha-ketoglutarate, and for the branched-chain alpha-keto acid dehydrogenase complex that is involved in amino acid catabolism (Singleton & Martin 2001). Some of these enzymes are also important in brain oxidative metabolism (Molina et al 2002).

Neurotransmitter biosynthesis

Thiamine is involved in the biosynthesis of a number of cell constituents, including the neurotransmitters acetylcholine and gamma aminobutyric acid (GABA).

DNA

Thiamine is involved in the synthesis of precursors of DNA, therefore thiamine use is increased in tumours.

Neuropsychological actions

Besides its involvement in neurotransmitter biosynthesis, thiamine is required for neurotransmission, nerve conduction, blood cerebrospinal fluid (CSF) barrier (BCSFB) functionality and muscle action. In the form of TTP, it concentrates in nerve and muscle cells and activates membrane ion channels. As such, thiamine deficiency is associated with neurological changes and suspected of contributing to the development of alcoholic peripheral neuropathy and Wernicke–Korsakoff's syndrome from a variety of aetiologies (D'Amour et al 1991, Nixon et al 2006). The most recent evidence from animal studies suggests that impaired BCSFB function, secondary to thiamine deficiency, allows passage of neuroactive substances into the brain, damaging the choroid plexus (Nixon et al 2006).

CLINICAL USE

Many of the clinical uses of thiamine supplements are conditions thought to arise from a marginal deficiency, but some indications are based on the concept of high-dose supplements acting as therapeutic agents. In practice, vitamin B_1 is usually recommended in combination with other B-group vitamins.

Deficiency: treatment and prevention

Thiamine supplements are traditionally used to treat or prevent thiamine deficiency states in people at risk (see *Secondary deficiency*).

Hyperemesis

Although thiamine supplementation will not reduce the symptoms of hyperemesis, it may be necessary in cases of hyperemesis gravidarum and hyperemesis due to gastroplasty in order to avoid deficiency states and the development of Wernicke's encephalopathy, which has been reported in these situations, although noted to be a rare consequence. It may be precipitated in part by intravenous fluids containing dextrose, and is more commonly seen when the patient's liver transaminases are elevated, which may contribute to the encephalopathy (Francini-Pesenti et al 2007, Gardian et al 1999, Seehra et al 1996, Spruill & Kuller 2002, Tan & Ho 2001, Togay-Isikay et al 2001, Toth & Voll 2001, Welsh 2005).

Alcoholism

In alcoholism, a state of decreased intake, absorption, utilisation and increased requirement for thiamine occurs, necessitating increased intakes to avoid deficiency states (D'Amour et al 1991). In cases of Wernicke's encephalopathy, monitoring of thiamine status and prophylactic intravenous treatment will inhibit the progression to Korsakoff's psychosis (Thomson & Marshall 2005). Ongoing research has revealed that the cerebellar neurotoxicity associated with excess alcohol is more likely mediated predominantly by thiamine deficiency than by direct ethanol cytotoxicity, as previously believed (Mulholland et al 2005); however, there is growing evidence of a strong negative synergy between the two that extends well beyond the increased need for thiamine as a result of alcohol consumption (Nixon et al 2006).

Total parenteral nutrition

Several case reports show that patients who have received TPN without proper replacement of thiamine are at risk of developing deficiency signs and Wernicke's encephalopathy (Francini-Pesenti et al 2007, Hahn et al 1998, van Noort et al 1987, Vortmeyer et al 1992, Zak et al 1991). Recent preliminary evidence suggests that current TN vitamin formulations are not sufficient to ensure thiamine repletion in all patients (Francini-Pesenti et al 2008).

Hyperthyroidism

Although a somewhat rare sequelae, a handful of case reports describe Wernicke–Korsakoff's syndrome in patients suffering thyrotoxicosis (Bonucchi et al 2008).

Surgical patients

Several recent case reports detailing Wernicke's encephalopathy in surgical patients highlight why this patient group should be considered 'high risk' for thiamine deficiency: malnutrition, high stress levels, vomiting and ileus, which together increase thiamine requirements substantially (Al-Nasser et al 2006, Francini-Pesenti et al 2007. Several authors suggest that thiamine deficiency may be latent in the preoperative patient, with surgery or postoperative TPN precipitating clinical manifestation and consequently recommend preoperative screening for thiamine status (Al-Nasser et al 2006.

Acute alcohol withdrawal

Several guidelines for the support of alcohol withdrawal recommend a dose of 100 mg thiamine administered intravenously or intramuscularly before routine administration of dextrose-containing solutions (Adinoff et al 1988, Erstad & Cotugno 1995).

Alzheimer's dementia (AD)

Thiamine status has been investigated and found, amongst other nutrients, to have an inverse relationship with cognitive function in the elderly (Nourhashemi et al 2000). More specifically, AD has been associated with reduced plasma levels of thiamine, according to several clinical studies (Gold et al 1995, 1998, Molina et al 2002). One study analysed cerebral cortex samples from autopsied patients with AD and found slight reductions in TDP levels compared with matched controls (Mastrogiacoma et al 1996). Others have demonstrated reduced activities of thiamine-dependent enzymes, together with a strong correlation between these reductions and the extent of the dementia in autopsied brains (Gibson & Blass 2007).

Proposed mechanisms for the relationship between thiamine and AD are varied, ranging from its role as an antioxidant and its critical contribution to the Krebs cycle to its involvement in the production of acetylcholine, disturbances of which have all been implicated in AD pathology (Bubber et al 2004, Butterfield et al 2002, Gibson & Blass 2007, Kruse et al 2004). Recent animal research points towards the shared features of thiamine deficiency and AD pathology in the brain, in particular, with increased oxidative stress and inflammation precipitating neuronal loss in specific brain areas and concomitant promotion of plaque formation (Karuppagounder et al 2008).

Investigation with high-dose thiamine supplementation in this population has produced mixed results (Blass et al 1988, Meador et al 1993, Mimori et al 1996). One double-blind, placebo-controlled, crossover study showed that a dose of 3000 mg thiamine/day produced higher global cognitive ratings as assessed by the Mini-Mental State Examination compared with a niacinamide placebo. However, there were no changes to clinical state and behavioural ratings (Blass et al 1988). Another clinical study of unknown design found positive results with a dose ranging between 3 and 8 g/day of thiamine (Meador et al 1993), whereas a long-term study using high-dose supplementation produced negative results (Mimori et al 1996).

Although promising overall, a 2001 Cochrane review stated that it is still not possible to draw any conclusions about the effectiveness of thiamine supplementation in AD (Rodriguez-Martin et al 2001). In practice, it is often used as part of a broad-spectrum approach with other B-group vitamins in age-related cognitive decline; however,

further research is required to determine whether this method produces more consistent results, particularly as an adjunct to standard pharmaceutical treatments (Gibson & Blass 2007).

Congestive heart failure (CHF)

A 2001 review concluded that there was insufficient evidence from large trials to confirm thiamine as a corrective treatment in CHF; however, prophylactic supplementation was worthwhile, considering the high prevalence of deficiency in this population (Blanc & Boussuges 2001). The largest and most recent trial since then was published in 2006 and confirmed that the incidence of deficiency is notable amongst CHF patients (Hanninen et al 2006). It is suspected that patients with existing heart failure are at increased risk of thiamine deficiency because of diuretic-induced depletion, advanced age, malnutrition and/or periods of hospitalisation.

A number of small interventional studies have assessed the effect of thiamine supplementation in patients with CHF with promising results. In one pilot study six patients treated with IV thiamine, such that their thiamine status returned to normal, resulted in increased left ventricular ejection fraction (LVEF) in four of five patients studied by ECG (Seligmann et al 1991). A randomised, placebo-controlled, double-blind study of 30 patients compared the effects of IV thiamine (200 mg/day) to placebo over 1 week followed by oral thiamine (200 mg/day) taken for 6 weeks. In the 27 patients completing the full 7-week intervention, LVEF rose by 22%. Other positive results have been reported from similar studies (Hanninen et al 2006). The current position of key researchers in this area is that, together with other micronutrients critical for myocardial energy production and control of oxidative stress (e.g. taurine), thiamine inadequacy is likely to exacerbate myocyte dysfunction and loss in this condition, making repletion an important therapeutic objective (Allard et al 2006).

Diabetes

Given thiamine's essential role in the key carbohydrate metabolic enzymes: transketolase, pyruvate dehydrogenase and alpha-ketoglutarate dehydrogenase and the precipitation of glucose toxicity secondary to thiamine deficiency (Nixon et al 2006), there is growing interest in the therapeutic potential of this nutrient in diabetes. Preliminary research of thiamine status in diabetic patients reveals significantly high rates of deficiency (≈75% of type 1 and 2 diabetics), secondary to greatly increased renal losses of this B vitamin (Thornalley et al 2007). These initial findings lead researchers to speculate that reduced thiamine availability may exacerbate diabetic metabolic dysfunction, particularly with respect to microvascular complications. Adding to the evidence of earlier in vitro studies demonstrated that thiamine improves endothelial function, while protecting against insulin-mediated vascular smooth muscle cell proliferation (Arora et al 2006).

A recent investigation into high-dose thiamine (100 mg taken three times daily) over 3 months in small sample of type 2 diabetes mellitus (T2DM) patients with microalbuminuria demonstrated reversal of early stage nephropathy in the treatment group, without altering glycaemic control, dyslipidaemia or blood pressure (Rabbani et al 2008). Another study employing thiamine, this time in IV form, improved endothelium-dependent vasodilation in hyperglycaemic patients (both diabetic and non-diabetic); however, the mechanism of action remains unclear (Arora et al 2006).

The assessment of thiamine adequacy in diabetic patients is confounded by the invalidity of standard diagnostic tests, e.g. red blood cell transketolase activity (Thornalley et al 2007).

Dysmenorrhoea

A Cochrane review of herbal and dietary therapies for primary and secondary dysmenorrhoea concluded that thiamine is an effective treatment when taken at 100 mg/day, although this conclusion is tempered slightly by its basis on only one large RCT (Wilson & Murphy 2001). That trial was a randomised, double-blind, placebo-controlled, crossover design conducted over 5 months in 556 women and procured a positive improvement in >90% of the treatment cycle versus <1% in the placebo phase. The improvements observed during treatment appeared to have lasting effects, even after cessation of supplementation, for up to 3 months (Gokhale 1996). Due to the dramatic 'success' of this study, it has attracted scepticism regarding its methodology; certainly a question is why, with such positive results, an attempt to replicate the findings has not been undertaken in over 9 years (Fugh-Berman & Kronenberg 2003).

OTHER USES

Cataracts

A case-controlled study of 72 patients found that thiamine supplementation reduced the incidence of cortical, nuclear and mixed cataracts (Leske et al 1991).

Coma

A general approach to patients presenting to hospital with coma is to ensure adequate oxygenation, blood flow and treatment with hypertonic glucose and thiamine (Alguire 1990, Buylaert 2000).

Epilepsy

A randomised, placebo-controlled study involving 72 patients with epilepsy who had received long-term phenytoin treatment alone or in combination

Clinical note — No protection against insect bites

One claim that has been around for many years is that high oral doses of certain B vitamins could act as a deterrent to insects such as mosquitoes. Principally, the myth has centred on thiamine. A recent review of prophylaxis against insect bites found that neither topical application nor oral dosing of thiamine is an effective preventative strategy (Rudin 2005).

with phenobarbital found that administration of thiamine (50 mg/day) over 6 months improved neuropsychological functions in both verbal and non-verbal IQ testing (Botez et al 1993). This study also found both folate supplementation and placebo ineffective.

Fatigue
B-group vitamins are often taken by the public to lessen the impact of 'stress' and provide an energy boost. In one study, thiamine 10 mg/day significantly increased appetite, energy intake, body weight, general wellbeing and decreased fatigue, compared with placebo in a group of 80 randomly chosen women from a population with known marginal deficiency (Smidt et al 1991). Thiamine supplementation also tended to reduce daytime sleep time, improve sleep patterns and increase activity.

HIV
Several neuropathological reports have described brain lesions characteristic of Wernicke's encephalopathy in patients with AIDS. One study found a 23% prevalence of thiamine deficiency in AIDS patients with no history of alcohol abuse (Butterworth et al 1991).

Neurogenic impotence
A dose of 25 mg thiamine taken orally resulted in normalisation of erection in a man with a history of chronic alcoholism and erectile dysfunction of 1 year's duration (Tjandra & Janknegt 1997). However, more recent evidence discussing the causes of neurogenic impotence suggests that thiamine deficiency is relatively rare (Finsterer 2005).

Maple syrup urine disease
Of four paediatric patients with maple syrup urine disease, three responded to thiamine therapy with a reduction in concentration of plasma and urinary branched-chain amino and keto acids (Fernhoff et al 1985).

Optic neuropathy
Several case reports suggest this condition can be caused by thiamine deficiency and successfully treated with supplementation. One case report of a man developing optic neuropathy as a result of receiving TPN without thiamine for 4 weeks found that supplementation with thiamine reversed the condition (Suzuki et al 1997). Two cases of symmetrical, bilateral optic neuropathy associated with thiamine deficiency were successfully treated with thiamine supplementation (Hoyt & Billson 1979).

DOSAGE RANGE
- Prevention of deficiency (adult Australian RDI): 1.1–1.2 mg/day.
- Treatment of marginal deficiency states: 5–30 mg/day.
- Critical deficiency: 50–100 mg IV or IM for 7–14 days, after which oral doses are used (Tanphaichitr 1999).
- CHF: 100 mg twice daily IV for 1–2 weeks, then 200 mg/day orally.
- Dysmenorrhoea: 100 mg/day orally.
- Support of alcohol withdrawal: 100 mg given IV or IM.
- Fatigue (when marginal deficiency likely): 10 mg/day.
- Type 2 diabetes mellitus: 100 mg three times daily.

Australian RDI
Females >13 years: 1.1 mg/day.
Males >13 years: 1.2 mg/day.

TOXICITY
Toxicity does not occur with oral thiamine as it is rapidly excreted by the kidneys (Tanphaichitr 1999), although there is some evidence that toxicity can occur with very large doses given parenterally (Jacobs & Wood 2003).

ADVERSE REACTIONS
Thiamine is well tolerated.

SIGNIFICANT INTERACTIONS

Antibiotics
Antibiotics can reduce the endogenous production of B-group vitamins by gastrointestinal flora, theoretically resulting in lowered B vitamin levels. The clinical significance of this is unclear — increase intake of vitamin B_1-rich foods or consider supplementation.

Iron
Iron precipitates thiamine, thereby reducing its absorption — separate doses by 2 h.

Loop diuretics
Chronic use may result in lowered levels of vitamin B_1 — increase intake of vitamin B_1-rich foods or consider long-term supplementation.

Other B vitamins
Thiamine deficiency commonly occurs in conjunction with poor B_2 and B_6 status (Jacobs & Wood 2003).

Sulfites
Concomitant intake may inactivate thiamine, which has been reported in TPN solutions (Bowman & Nguyen 1983).

Tannins
Tannins precipitate thiamine, thereby reducing its absorption — separate doses by 2 hours.

CONTRAINDICATIONS AND PRECAUTIONS

Cancer
There is some evidence of thiamine being associated with nucleic acid ribose synthesis of tumour cells in its biologically activated form (Boros 2000). As such, thiamine may theoretically increase tumour formation. To date, the clinical relevance of this finding has not been explored.

PRACTICE POINTS/PATIENT COUNSELLING

- Thiamine is necessary for healthy functioning and is involved in carbohydrate and protein metabolism, the production of DNA and several neurotransmitters and nerve and muscle functions.
- Supplements are used to treat deficiency or prevent secondary deficiency in people at risk (e.g. alcoholism, malabsorption syndromes, hyperemesis, chronic diarrhoea, hyperthyroidism, pregnancy, lactation, fever, acute infection, folate deficiency, strenuous physical exertion, breastfeeding, adolescent growth, severe liver disease and chronic use of loop diuretics). There is a higher incidence of deficiency in people with CHF; however, it is not known whether correction of the deficiency will improve disease symptoms.
- High-dose thiamine supplements relieve symptoms of dysmenorrhoea, according to one large RCT.
- Additionally, some early research has found an association between Alzheimer's dementia and low plasma thiamine levels, with supplementation producing some benefits; however, further investigation is still required.
- Oral supplements are non-toxic, but should be used with caution in patients with cancer.

PREGNANCY USE

Safe during pregnancy and lactation.

PATIENTS' FAQs

What will this vitamin do for me?

Thiamine is necessary for healthy functioning and is involved in carbohydrate and protein metabolism, the production of DNA, several brain chemicals and nerve and muscle functions. Supplements are taken to avoid deficiency states that can occur, for instance, in alcoholism, extreme vomiting, chronic diarrhoea or malabsorption syndromes. In high doses, it may relieve symptoms of painful menstruation and may be a useful adjunct in CHF.

When will it start to work?

Thiamine supplements can have dramatic effects on deficiency states within 24 h. The response time for other conditions, such as dysmenorrhoea and CHF, also appears to be reasonably fast. Within two menstrual cycles, supplementation produced marked reductions in dysmenorrhoea, and CHF patients treated for only 7 weeks showed positive responses.

Are there any safety issues?

Taken orally, thiamine is considered non-toxic. People with cancer should consult with their physician before taking high-dose thiamine supplements.

Vitamin B_2 — riboflavin

BACKGROUND AND RELEVANT PHARMACOKINETICS

Riboflavin is a water-soluble B-group vitamin that is sensitive to light and alkali conditions. Once absorbed, it is converted into its active form. Riboflavin works as a component of two primary coenzymes, flavin adenine dinucleotide (PAD) and flavin mononucleotide (FMN). Both of these belong to the class known as the flavin coenzymes, all of which are active in redox reactions involving hydrogen transfer and consequently important for the body's production of adenosine triphosphate (ATP). Although some organs (such as the liver) have relatively high concentrations of flavin coenzymes, the flavin seems to be present as coenzyme moieties of flavin holoenzymes, which are fully functional.

There are two sources of riboflavin: dietary and bacterial, whereby the vitamin is produced by normal gastrointestinal microflora. The amount of bacterially synthesised riboflavin depends on the type of diet consumed, with higher synthesis resulting from intake of vegetable-based diets than from meat-based diets (Said 2004). For direct dietary sources, see *Food sources* below.

Riboflavin uptake occurs mainly in the proximal part of the small intestine and involves a specialised, Na^+-independent carrier-mediated system. Adaptive changes alter the number and/or activity of carriers, and uptake is saturable when large pharmacological doses of riboflavin are ingested. There is evidence that bioavailability is optimal once 25 mg has been reached, and doses in excess of this show reduced or unaltered absorption efficacy

(Groff & Gropper 2009). The absorption of vitamin B_2 is enhanced when it is consumed in flesh foods and impeded by the presence of divalent metals (e.g. zinc, iron, copper and manganese).

FOOD SOURCES

The main food sources are organ meats, yeast products (including Vegemite), almonds, wheatgerm, wild rice and mushrooms. Vitamin B_2 is also found to a lesser extent in dairy products and vegetables. Maximum loss during cooking is 75% (Wahlqvist 2002).

DEFICIENCY SIGNS AND SYMPTOMS

Primary deficiency

Primary deficiency is associated with inadequate dietary intake, such as poor consumption of milk and other animal products. Primary deficiency is reported to be more common in the elderly and adolescent girls.

Secondary deficiency

Secondary deficiencies can develop in chronic diarrhoea, liver disease, chronic alcoholism, adrenal or thyroid hormone insufficiency, and postoperative situations in which total parenteral nutrition (TPN) solutions lack riboflavin. In most cases, riboflavin deficiency is accompanied by other vitamin deficiencies, such as deficiencies of vitamin B_6, niacin and folic acid. Drugs that impair riboflavin absorption or utilisation by inhibiting the conversion of the vitamin to the active coenzymes include tricyclic antidepressants, chemotherapy drugs and psychotropic agents. There is also evidence suggesting an apparent increase in riboflavin requirements with increased physical exercise.

Signs and symptoms of deficiency

The body's 'storage capacity' is sufficient to provide riboflavin for 2–6 weeks when nutritional status is normal, but during protein deficiency the stores are significantly reduced.

Initial symptoms of riboflavin deficiency are often non-specific and include: weakness, fatigue, mouth pain and personality changes. Isolated riboflavin deficiency seldom occurs and is usually associated with a deficiency of other B-group vitamins.

Other signs and symptoms are:

- angular stomatitis, cracked lips, cold sores and cheilosis
- glossitis, magenta tongue (Lo 1984)
- failure to grow in children
- ocular and visual disturbances, with symptoms such as burning, itching, sensitivity to light and conjunctivitis
- scaly and greasy dermatitis affecting the nasolabial folds, ears, eyelids, scrotum and labia majora (Lo 1984)
- desquamative dermatitis
- hair loss
- poor wound healing.

Of interest, a study of 154 pregnant women at increased risk of preeclampsia found that those who were riboflavin deficient were 4.7-fold more likely to develop the condition than those with adequate levels (Wacker et al 2000).

MAIN ACTIONS

Riboflavin is involved in many different biological processes and is essential for maintaining good health. It is involved in ATP production, is essential for immune function, tissue repair processes and general growth (it is required for the healthy growth of skin, nails and hair), and plays a key role in fatty acid oxidation and the metabolism of several other B vitamins.

Riboflavin has important antioxidant activity in itself, but also as part of the FAD-dependent enzyme glutathione reductase. It also activates vitamin B_6 and folate.

CLINICAL USE

A number of clinical trials have been conducted in which patients presenting with different condition have subsequently been found to have riboflavin deficiency. Treating the deficiency in some of these cases has been shown to improve the initial presenting condition.

Wound healing

Riboflavin deficiency lengthens the time to epithelialisation of wounds, slows the rate of wound contraction and reduces the tensile strength of incision wounds in vivo. Total collagen content is also significantly decreased, suggesting riboflavin deficiency will slow down wound-healing rate (Lakshmi et al 1989).

Migraine headaches: prophylaxis

Three clinical studies of varying design have found that treatment with high-dose riboflavin (400 mg) can reduce the frequency of migraine headaches; however, one double-blind study that used it in combination with magnesium and feverfew failed to show beneficial effects over low-dose riboflavin (25 mg).

The first was an open pilot study testing the effects of 400 mg riboflavin over 3 months in 49 patients. Active treatment produced positive results, with 59% of the treatment group experiencing a reduction in migraine frequency of at least 50% (Schoenen et al 1994). Based on these results, a second study with 55 subjects was conducted using a randomised, placebo-controlled design, with similar positive findings (Schoenen et al 1998). In 2004 an open-label study retested the same high dose of vitamin B_2 over 6 months and once again showed a significant reduction in headache frequency, from 4 days/month at baseline to 2 days/month after 3 and 6 months of treatment ($P < 0.05$). Use of abortive drugs reduced from 7 units/month to 4.5 units/month; however, the duration and intensity of each episode did not change significantly (Boehnke et al 2004).

Alternatively, a randomised, double-blind, controlled study using a combination of vitamin B_2 (400 mg), magnesium (300 mg) and feverfew (100 mg) failed to show benefits over riboflavin 25 mg. Both groups showed a comparable significant reduction in number of migraines, migraine day and migraine index; however, in neither group was frequency successfully reduced by more than 50%, which was the primary outcome (Maizels et al 2004). Interestingly, the response obtained was greater than the placebo response reported in other migraine prophylaxis trials.

Clinical note — Causes of migraine

Numerous theories exist to explain the underlying pathology of migraine headache. One theory proposes a deficit of mitochondrial energy metabolism, as patients with migraine show decreased brain mitochondrial energy reserve between attacks. Interestingly, patients with mitochondrial encephalomyopathy, lactic acidosis and stroke-like episodes (MELAS) exhibit impaired mitochondrial energy metabolism, producing migraine-like headaches, which are in part ameliorated by prophylactic B_2 (Magis et al 2007).

Accordingly, riboflavin coenzyme Q10 and lipoic acid, as enhancers of mitochondrial energy efficiency, have been tested for prophylactic activity in migraine and appear to be promising agents (Magis et al 2007, Schoenen et al 1994). Recent studies in experimental models add to our knowledge of the actions of riboflavin in migraine, with confirmation that it produces antinociception and anti-inflammatory effects. The analgesic activity observed is independent of opioid mechanisms (Granados-Soto et al 2004).

Comparative trial

A clinical trial comparing riboflavin supplementation with standard beta-adrenergic antagonists found that both treatments significantly improved the clinical symptoms of migraine headache (Sandor et al 2000). Analysis of their effects on cortical potentials showed that the two treatments achieve these results by working through different mechanisms.

Age-related cataract prevention

Cataract was shown to be associated with riboflavin deficiency in animals in the 1930s and subsequently with deficiencies of amino acids, vitamins and some minerals (Wynn & Wynn 1996). This has been confirmed in human studies, in which lens opacities have been associated with lower levels of riboflavin, vitamins A, C and E, iron, and protein status (Leske et al 1995, Mares-Perlman et al 1995).

Glutathione reductase is a key enzyme involved in lens protection. Riboflavin levels indirectly influence glutathione reductase activity, increasing the ability of the lens to deal with free radical formation (Head 2001). One study documented severe glutathione reductase deficiency in 23% of human lens epithelium specimens, possibly reflecting a dietary deficiency of riboflavin (Straatsma et al 1991). Another study found that a significant number of people with cataracts have inactive epithelial glutathione reductase (Horwitz et al 1987).

A large cross-sectional survey of 2873 volunteers aged 49–97 years detected a link between dietary vitamin supplement and a lower incidence of both nuclear and cortical cataract. Vitamin A, niacin, riboflavin, thiamine, folate and vitamin B_{12} all appeared to be protective, either in isolation or as constituents of multivitamin preparations (Kuzniarz et al 2001).

A recent sample of 408 women from the Nurses' Health Study aged 52–74 years at baseline participated in a 5-year study that assessed nutrient intake and the degree of nuclear density (opacification).

Clinical note — Age-related cataract and antioxidants

Age-related cataract is an important public health problem, because approximately 50% of the 30–50 million cases of blindness worldwide result from leaving the condition untreated (Jacques 1999). The mechanisms that bring about a loss in transparency include oxidation, osmotic stress and chemical adduct formation (Bunce et al 1990). Besides traditional risk factors such as diabetes, nutrient deficiency is also being considered, particularly nutrients with antioxidant properties.

Findings revealed that the geometric mean 5-year change in nuclear density was inversely associated with the intake of riboflavin ($P = 0.03$) and thiamin ($P = 0.04$), and most significantly with the duration of vitamin E supplement use ($P = 0.006$) (Jacques et al 2005).

The evidence currently suggests that higher intakes of riboflavin protect against the progression of age-related lens opacification.

Breast cancer — adjunctive treatment to tamoxifen

Riboflavin's importance is recognised in a range of terminal disease states, most notably in breast cancer, where its cellular absorption is significantly enhanced (Bareford et al 2008). Based on its established antioxidant properties, its role in maintaining epithelial integrity, and its influence on prostaglandin synthesis and glutathione (GSH) metabolism (Premkumar et al 2008a), vitamin B_2 (10 mg) has been trialled in combination with coenzyme Q10 (100 mg) and niacin (50 mg) (known as CORN) together with tamoxifen in breast cancer patients. The results of the studies have consistently demonstrated augmenting actions — enhanced manganese superoxide dismutase (MnSOD) expression, resulting in prevention of cancer cell proliferation (Premkumar et al 2008b), reduction of lipid peroxides (which are elevated in breast cancer and associated with tumour promotion) (Yuvaraj et al 2008), reduced tumour markers CEA and CA 15-3 and reduced serum cytokines (IL1 beta, IL6, IL8, TNFA & VEGF) (Premkumar et al 2008a). In addition to this, CORN supplementation reduced pro-angiogenic markers, with a corresponding increase in anti-angiogenic markers. Given that the growth and metastasising capacity of any tumour (but particularly of breast tumours) is dependent upon angiogenesis, this could represent a means to improved prognoses (Premkumar et al 2008a). Finally, CORN supplementation was shown to moderate some of the negative side effects of tamoxifen treatment, with normalisation of lipid and lipoproteins following 90 days of treatment in postmenopausal breast cancer patients (Yuvaraj et al 2007).

Role in folate and pyridoxine metabolism and the methylation pathologies

Effective one-carbon metabolism relies on nutrients beyond folate, B_6 and B_{12} — most notably B_2, which, although attracting significantly less research

attention, remains critical. Riboflavin, as FAD, is the cofactor for methylenetetrahydrofolate reductase (MTHFR), responsible for converting folate into its active form (Powers 2003, 2005, Sharp et al 2008). Consistent with this, there is emerging evidence of substantial interplay between folate and riboflavin in conditions previously associated only with folate deficiency or ameliorated by folate treatment. For example, plasma levels of vitamin B_2 and homocysteine have been shown to correlate (de Vogel et al 2008), especially in individuals with the MTHFR C677TT genotype (McNulty et al 2006). Preliminary studies employing combinations of folate (400 microgram) and riboflavin (5 mg) have demonstrated improved efficacy over folate alone, for example in colorectal cancer (Powers 2005). Additionally, high doses of folate alone have been reported to modestly but significantly reduce vitamin B_2 levels (Powers 2005). Taken together with the knowledge that riboflavin is central to pyridoxine metabolism (McCormick 2000), there is growing interest in the therapeutic potential of riboflavin in pathologies associated with poor methylation.

Sickle cell anaemia

Riboflavin supplementation (5 mg twice daily for 8 weeks) in patients with sickle cell anaemia resulted in improved haematological measurements compared with controls, suggesting that riboflavin enhances erythropoiesis (Ajayi et al 1993).

Rheumatoid arthritis

One study has suggested that patients with higher pain scores and active disease are at significantly greater risk of riboflavin deficiency than those with inactive disease (Mulherin et al 1996). In this study of 91 patients, pain score, articular index, C-reactive protein and erythrocyte sedimentation rate were all increased in those patients exhibiting riboflavin deficiency (all $P < 0.02$). It is unclear whether riboflavin deficiency influences pain threshold or is a result of the disease.

Other uses

Riboflavin is also used to treat carpal tunnel syndrome and acne, although only case reports are available (Folkers et al 1984).

DOSAGE RANGE

- Migraine prevention: 400 mg/day, taken for at least 3 months.
- Treating deficiency states: 10 mg/day.
- As an adjunct to tamoxifen in breast cancer treatment: 10 mg/day together with coenzyme Q10 100 mg/day and niacin 50 mg/day — based on preliminary evidence.

Australian RDI

<70 years
- Women: 1.1 mg/day.
- Men: 1.3 mg/day.

>70 years
- Women: 1.3 mg/day.
- Men: 1.6 mg/day.

Intake of vitamin B_2 causes a characteristic bright yellow-orange discolouration to urine.

TOXICITY

Riboflavin is considered an extremely safe supplement. Even at the high doses (400 mg) used in some of the trials, riboflavin remains non-toxic.

ADVERSE REACTIONS

General side effects noted in trials using high doses were reasonably uncommon, but included diarrhoea and polyuria (Bianchi et al 2004). One case of anaphylaxis has been reported (Ou et al 2001).

SIGNIFICANT INTERACTIONS

Certain medicines can increase the body's requirements for riboflavin.

Antibiotics

Antibiotic drugs can reduce endogenous production of B-group vitamins — increase intake of vitamin B_2.

Oral contraceptive pill

The OCP may increase demand for vitamin B_2 (Pelton et al 2000) — consider increasing intake with long-term use.

Tricyclic antidepressants

Reduces the absorption of riboflavin — may increase riboflavin requirements (Pelton et al 2000).

Amitryptyline

Increases the renal excretion of riboflavin (Bianchi et al 2004) — consider increased dietary intake with long-term use.

CONTRAINDICATIONS AND PRECAUTIONS

None known.

PREGNANCY USE

Considered safe.

PRACTICE POINTS/PATIENT COUNSELLING

- Vitamin B_2 deficiency signs include poor wound healing, hair loss, greasy dermatitis, ocular disturbances, failure to grow in children, angular stomatitis, cold sores, cracked lips and magenta tongue.
- Besides inadequate intake, deficiency can also result from chronic diarrhoea, liver disease and chronic alcoholism.
- There is some evidence suggesting that high-dose supplements (400 mg daily) significantly reduce the frequency of migraine headaches.
- Preliminary evidence suggests that regular supplementation with a multivitamin may also reduce the risk of developing cataracts.
- Supplementation results in a characteristic yellow-orange discolouration of urine.

PATIENTS' FAQs

What will this vitamin do for me?

Vitamin B_2 is essential for health and is involved in many different biochemical processes in the body. Research has suggested that when taken in high doses it can significantly reduce the incidence of migraine headaches.

When will it start to work?

Deficiency is reversed rapidly with supplementation. If using riboflavin to prevent migraine headaches, 3–4 months' treatment is required to see significant effects.

Are there any safety issues?

The vitamin is considered a safe nutrient.

Vitamin B_3 — niacin

HISTORICAL NOTE The term 'niacin' is used interchangeably with nicotinic acid, and is also used collectively to include nicotinamide (or niacinamide), the amide form of nicotinic acid. Niacin originally derived its name from its discovery as an oxidation by-product of nicotine, and has been used generically since the 1940s to label foods and avoid association with nicotine, the alkaloid from tobacco. Nicotinic acid was the first hypolipidaemic agent shown to decrease the incidence of secondary myocardial infarction and reduce total mortality in these patients (Wilson et al 1991).

BACKGROUND AND RELEVANT PHARMACOKINETICS

Vitamin B_3 (niacin) is a water-soluble vitamin of the B complex family. Both nicotinic acid and nicotinamide are absorbed in the stomach and small intestine by passive diffusion at high doses, or by sodium-dependent facilitated diffusion at low doses, and excreted in the urine. Recent studies suggest that niacin uptake may be regulated by an acidic pH-dependent carrier-mediated system and protein-tyrosine-kinase (PTK)-mediated pathway (Nabokina et al 2005). The immediate-release form of nicotinic acid reaches peak concentration at 45 minutes and the extended release form in 4–5 hours. While nicotinamide can be directly converted to nicotinic acid, nicotinic acid must undergo a number of metabolic steps to produce nicotinamide adenine dinucleotide + (NAD+) before being converted to nicotinamide (Hendler & Rorvik 2001, Wilson et al 1991). The body's niacin requirement is also met by the biosynthesis of niacin from tryptophan, an amino acid. It has been estimated that each 60 mg excess of tryptophan (after protein synthesis) is converted to approximately 1 mg of niacin. In the absence of sufficient levels of vitamin B_3, the body will preferentially convert tryptophan to B_3. Niacin is widely distributed throughout the body and concentrates in the liver, spleen and adipose tissue. It is finally excreted by the kidneys.

Common forms available

The term niacin is used to refer to both nicotinic acid (niacin) and nicotinamide (niacinamide). Niacin is also referred to as vitamin B_3.

The immediate-release form, which requires more regular dosing, is associated with significant vasodilation ('flushing'), whereas the sustained-release form is associated with an increased risk of adverse events. Extended-release forms of niacin allow once-daily dosing and avoid much of the flushing and hepatotoxicity of the immediate- and sustained-release preparations (Sadovsky 2002).

FOOD SOURCES

Organ and muscle meats, lamb's liver, beef, poultry, fish, yeast, legumes, peanuts, Vegemite, yeast, wheat bran and fruit all contain vitamin B_3. Trace amounts are found in vegetables and eggs and, although milk contains only small amounts of B_3, it is a good source of tryptophan, which can be converted to B_3 in the body. In cereals such as corn and wheat it is present in a bound form, such as glycoside niacytin, which is unavailable to the body and has negligible nutritional value. Soaking corn in an alkaline solution such as lime helps to increase B_3 bioavailability.

Maximum loss in cooking is 75% (Wahlqvist 2002).

DEFICIENCY SIGNS AND SYMPTOMS

Pellagra is a deficiency syndrome of vitamin B_3, due to inadequate conversion of tryptophan to niacin or a lack of dietary niacin or tryptophan. The main symptoms are often referred to as 'the four Ds' (Jacobs & Wood 2003):

- diarrhoea
- dermatitis — primarily on sun-exposed areas such as the face, hands, feet and arms. The rash starts as red, itchy areas that develop vesicles, blisters, scales and fissures. At the final stage, the skin becomes thickened, lichenified and hyperpigmented (Hendler & Rorvik 2001).
- dementia — may include aggressiveness and cloudy thinking (Llancapi et al 1998)
- death — if left untreated, vitamin B_3 deficiency can be fatal.

Vitamin B_3 deficiency may be found in conjunction with other deficiencies and may be associated with peripheral neuropathy. Early signs include anorexia, weakness, anaemia, glossitis, redness on sun-exposed areas and photosensitivity. Inadequate niacin status (niacin ratio ≤ 1) has been reported in 26.7% of older adults (Paulionis et al 2005).

Primary deficiency

This usually occurs in areas where maize (Indian corn) forms a major part of the diet. Bound niacin, found in maize, is not assimilated in the intestinal tract unless it has been previously treated with alkali, as in the preparation of tortillas. Corn protein is also deficient in tryptophan. Amino acid imbalance may also contribute to deficiency, since pellagra is common in India among people who eat millet with a high leucine content.

In Western industrialised countries such as Australia, New Zealand and USA, vitamin B_3 deficiency is mostly associated with conditions that affect the person's nutritional intake such as alcoholism, mental illness or homelessness. It may also occur in anorexia nervosa, where dietary niacin and tryptophan are deficient (Prousky 2003).

Secondary deficiency

This may develop in conditions associated with diarrhoea, cirrhosis or malabsorption, as well as after extensive postoperative use of parenteral nutrition lacking adequate niacin. Pellagra may occur during prolonged isoniazid therapy (the drug replaces nicotinamide in NAD), in malignant carcinoid tumour (tryptophan is diverted to form 5-hydroxytryptamine), and in Hartnup disease, an autosomal recessive disorder in which there is defective conversion of tryptophan to niacin (Beers & Berkow 2003). It has also been observed in Crohn's disease, most likely due to malnutrition and intestinal malabsorption (Abu-Qurshin et al 1997).

MAIN ACTIONS

Vitamin B_3 is involved in a wide range of biological functions, such as energy production, fatty acid synthesis, cholesterol and steroid synthesis, signal transduction, regulation of gene expression and maintenance of genome integrity. Other functions of vitamin B_3 include the regulation of blood sugar, antioxidant mechanisms and detoxification reactions (IMG 2006).

Niacin is a dietary precursor for the coenzymes NAD+ and nicotinamide adenine dinucleotide phosphate (NADP), which are involved in a number of metabolic functions such as DNA synthesis (Hageman & Stierum 2001), glycolysis, fatty acid

synthesis and cellular respiration (Kobayashi & Shimizu 1999). NAD+ exerts potent effects through a number of enzymes that alter protein function, regulate apoptosis, DNA repair, stress resistance, metabolism and endocrine signalling (Sauve 2008). NADH, the reduced form of beta-nicotinamide adenine dinucleotide, is also synthesised from niacin (B_3) and is required to supply protons for oxidative phosphorylation (Depeint et al 2006). Like chromium, vitamin B_3 is an important component of glucose tolerance factor. Niacin can also be preferentially converted from tryptophan, and as a result a deficiency of niacin can impact on other functions of tryptophan, such as neurotransmitter production.

Lipid-lowering

Large doses of niacin (nicotinic acid) reduce total cholesterol, LDL-cholesterol, triglycerides and lipoprotein(a) levels and also markedly raise HDL-cholesterol levels (Illingworth et al 1994). In human trials extended-release niacin (2 g/day) lowers plasma TG levels and raises plasma HDL, increases apolipoprotein A-I concentrations and production, as well as enhancing clearance of TG-rich lipoproteins apoB-100 and apoB-48 (Lamon-Fava et al 2008). The beneficial effects of niacin in reducing triglycerides and lipoproteins that contain apolipoprotein-B (such as VLDL and LDL) are thought to be mediated by inhibiting fatty acid mobilisation from adipose tissue triglyceride stores and increasing intracellular apolipoprotein-B degradation, resulting in decreased secretion of VLDL and LDL particles (Ganji et al 2003). The cardioprotective properties of HDL-cholesterol appear to be due to its involvement in processes such as reverse cholesterol transport and inhibition of LDL-cholesterol oxidation (Ganji et al 2003, Kwiterovich 2000).

Anti-atherogenic

In addition to its lipid-lowering ability, preliminary studies suggest that niacin inhibits vascular inflammation by decreasing endothelial reactive oxygen species (ROS) production and subsequent LDL oxidation and inflammatory cytokine production, key events in the atherogenic process (Ganji et al 2009).

Impairs glucose regulation

Although niacin is an important part of glucose tolerance factor, in high doses it may impair glucose regulation, resulting in insulin resistance, increased insulin secretion and increased fasting blood glucose in patients with type 2 diabetes, although some authors suggest that niacin is both safe and effective in diabetes (Meyers et al 2004).

Interestingly, nicotinamide has also been shown to cause insulin resistance, resulting in increased insulin secretion in healthy subjects with a family history of type 1 diabetes (Greenbaum et al 1996).

Modest increases in fasting blood glucose levels have been noted in a number of clinical trials (Elam et al 2000, Goldberg 1998, Rindone & Achacoso 1996), although other trials have found that changes in fasting blood glucose reverted to normal at 4 months (Grundy et al 2002) and 8 months (Zhao et al 2004).

In practice, this effect on glucose regulation may not be clinically significant (Gardner et al 1997, Guyton 2004, Meyers et al 2004, Zhao et al 2004) and the potential benefits of improved lipid control in diabetic patients for whom other lipid-lowering medications provide inadequate control may outweigh any concerns. Nevertheless hypoglycaemic medications may need to be monitored and adjusted if necessary (Fonseca 2003).

Antioxidant

Niacinamide has been shown in vitro to have an antioxidant activity comparable to that of ascorbic acid (Hageman & Stierum 2001).

Protects beta-cells in the pancreas

Nicotinamide has been shown to protect beta cells from inflammatory insults and to improve residual beta-cell function in patients after onset of type 1 diabetes (Lampeter et al 1998). It may also prevent damage to beta cells by the immune system as a result of its antioxidant effects (Anderson 1994).

Chondroprotection

The generation of IL-1 in the synovium and subsequent induction of nitric oxide (NO) synthase is crucial to the pathogenesis of osteoarthritis. The ability of niacinamide to suppress cytokine-mediated induction of NO synthase in a number of types of cells (McCarty & Russell 1999) provides a theoretical basis for its use as a chondroprotective agent.

Chemoprotection

The dietary status of niacin has the potential to affect DNA repair, genomic stability and the immune system, thus influencing cancer risk (Kirkland 2003), and increased demand may occur in many malignancies, including primary hepatoma (Jacobs & Wood 2003).

In vitro studies have shown that NAD+ is important for activity of PARP-1, an enzyme that is thought to be important for genomic stability. In vitro and animal studies have indicated that niacin deficiency increases genomic instability and may increase the risk of certain tumours. While NAD+ is niacin dependent, high doses of nicotinamide inhibit PARP-1 in vitro; hence, the effects may be dose dependent (Hageman & Stierum 2001). Niacin as a precursor for NAD+ also inhibits DNA strand breakage in vitro and stimulates repair (Weitberg & Corvese 1990).

Neuroprotective

In experimental models of Parkinson's disease, high doses of nicotinamide, a precursor for the coenzyme beta-nicotinamide adenine dinucleotide (NAD+), decreased oxidative stress and improved mitochondrial and motor function (Jia et al 2008). It has also been shown to preserve both neuronal and vascular cell populations in brain injury, and affect both intrinsic cellular integrity and extrinsic

cellular inflammation suggesting potential use in neurodegenerative diseases (Li et al 2004).

CLINICAL USE

Deficiency

Severe deficiencies of niacin and tryptophan, a precursor from which the body can synthesise niacin, are the principal causes of pellagra.

Anorexia nervosa

The most common features of pellagra in patients with anorexia nervosa include erythema on sun-exposed areas, glossitis and stomatitis. A trial of supplementation with 150–500 mg for 24–48 hours will quickly determine if symptoms are due to pellagra (Prousky 2003).

HIV and tryptophan depletion

A pellagra-like state can develop in malnourished patients with HIV and this may be due to impaired niacin status (Monteiro et al 2004) and result in tryptophan depletion. As tryptophan is preferentially converted to vitamin B_3 (if B_3 is depleted), a trial was conducted using high-dose niacin for 2 months in HIV patients and it was found that the high-dose niacin increased plasma tryptophan levels by 40% (Murray et al 2001).

An open, prospective trial has also concluded that extended-release niacin therapy is safe and effective for the treatment of dyslipidaemia associated with antiretroviral therapy; 2000 mg/day was given to 14 subjects for 14 weeks and resulted in significant reductions in serum levels of triglycerides, total cholesterol and non-HDL cholesterol (Gerber et al 2004).

Depression

As tryptophan is a precursor to serotonin, the preferential conversion of tryptophan to B_3 in deficiency states may theoretically result in serotonin depletion. If sufficiently severe, this could produce symptoms of depression.

Hypercholesterolaemia and hypertriglyceridaemia

Niacin has been widely used since the 1950s as a pharmacological agent to regulate abnormalities in plasma lipid and lipoprotein metabolism and in the treatment of atherosclerotic cardiovascular disease (Ganji et al 2003). Large doses of niacin reduce total cholesterol, LDL cholesterol, triglycerides and lipoprotein(a) levels, and also markedly raise HDL cholesterol levels (Illingworth et al 1994). According to a recent meta-analysis, effects on LDL cholesterol and triglycerides appear to be more significant in females, especially at doses of >1500 mg/day (Goldberg 2004).

Extended-release niacin (nicotinic acid) has been evaluated in at least four randomised, placebo-controlled trials, with the most efficacious results occurring at doses of 1500–2000 mg/day (Goldberg 1998, Grundy 2002, Guyton et al 2000, Morgan et al 2003). Results were dose- and time-dependent, with trials ranging in length from 4 to 16 weeks. At the 1500 and 2000 mg doses, reductions were noted in total cholesterol (–7 to –12.1%); total cholesterol to HDL cholesterol ratio (–17 to –22%); LDL cholesterol (0 to –7%); triglycerides (–16 to –36%); and lipoprotein(a) (–7 to –23.6%). One trial noted a particular decrease in the smaller, more atherogenic, dense LDL particles and an increase in the larger, cardioprotective HDL particles (Morgan et al 2003). HDL cholesterol increased by 21–25.8% and apolipoprotein A-I levels were reported in one study to have increased 9–11% (Guyton et al 2000). The main side effects reported were flushing, a 5% increase in fasting blood glucose, pruritis and rash (Goldberg 1998).

While existing guidelines for the prevention and treatment of coronary artery disease tend to focus on reducing LDL cholesterol, there is growing evidence linking low HDL cholesterol levels with an increased risk of atherosclerosis. As niacin significantly increases HDL cholesterol, and may also improve total cholesterol, LDL cholesterol and triglyceride levels, as well as exhibiting antioxidant,

Clinical note — Major lipids affecting cardiovascular disease risk

Cardiovascular risk is predicted by a number of factors; however, the major lipids involved are LDL cholesterol lipoprotein(a), triglycerides and HDL cholesterol. Furthermore, LDL particle size and number are associated with different levels of atherogenicity.

A reduction in HDL cholesterol and an increase in triglycerides and LDL cholesterol has been associated with an increased risk of cardiovascular disease. On the other hand, high HDL cholesterol is protective against atherosclerosis and is inversely related to risk of early coronary heart disease (Packard et al 2002). Its cardioprotective properties appear to be due to its involvement in processes such as reverse cholesterol transport and inhibition of LDL-cholesterol oxidation (Kwiterovich 2000). It has been suggested that niacin has the potential to regress atherosclerosis because of its ability to affect reverse cholesterol transport out of vessel walls (Rubic et al 2004).

Furthermore, the LDL phenotype B, characterised by small, dense LDL particles, is associated with increased atherogenicity compared to phenotype A, and niacin increases LDL particle size from small LDL to the less atherogenic, large LDL subclasses (Morgan et al 2004). The frequency of the LDL phenotype B increases as HDL's decrease and triglycerides increase.

Lipoprotein(a) has been identified as an independent risk factor for premature coronary artery disease and aggravates the atherogenic effect of diabetes mellitus (Wassef 1999).

A 2002 review highlights the ability of niacin to effectively lower triglycerides, raise HDL cholesterol and shift LDL particles to the less atherogenic phenotype A — all important factors that reduce the risk of cardiovascular disease (Ito 2002).

anti-inflammatory and other benefits, it is a prime candidate for the prevention and treatment of atherosclerosis (Sanyal et al 2007). A 2002 review suggests that niacin is the 'only agent currently available that favourably affects all components of the lipid profile to a significant degree' and has the greatest effect on HDL levels (Pieper 2002). In a double-blind RCT, 107 patients with coronary artery disease received 1000 mg/day extended-release niacin (ER-niacin) or a placebo for 12 weeks. ER-niacin improved endothelial dysfunction, triglycerides ($P = 0.013$), LDL cholesterol ($P = 0.013$) and HDL cholesterol ($P < 0.0001$). However, best results were seen in patients with low baseline HDL cholesterol (Warnholtz et al 2009).

Niacin may also be combined with chromium (Bolkent et al 2004, Shara et al 2005, Yanardag et al 2005) or phytosterols (Yeganeh et al 2005) for synergistic effects.

Combined therapy: statins and niacin

Although monotherapy with statin drugs (HMG-CoA reductase inhibitors) causes significant reductions in LDL cholesterol, they provide only modest improvements in triglycerides and HDL cholesterol. Niacin, on the other hand, provides significant reduction of triglycerides and enhancement of HDL cholesterol levels, although reductions in LDL cholesterol are less significant. As a result, combinations of these lipid-modifying agents will better address lipid abnormalities and improve clinical outcomes (Ito 2002, Levy & Pearson 2005).

In practice, the concurrent use of niacin with a statin has demonstrated improved outcomes in patients for whom monotherapy was unable to achieve adequate lipid control (Gardner et al 1997, Guyton & Capuzzi 1998). The combination may also slow the progression of atherosclerosis in individuals with known coronary heart disease and moderately low HDL-cholesterol (Taylor et al 2004).

Numerous studies exist to support the safe and effective use of extended-release niacin with lovastatin (Armstrong et al 2004, Bays et al 2003, Rubenfire 2004), simvastatin (Kaur et al 2004, Zhao et al 2004), pravastatin (Gardner et al 1997), and rosuvastatin (Capuzzi et al 2003).

In a 24-week trial of 319 high-risk patients with predominantly mixed dyslipidaemia who received simvastatin alone (20 mg/day) or a combination of simvastatin (20 mg/day) plus extended release niacin (1000 or 2000 mg/day), there was a significant dose-dependent decrease in non-HDL cholesterol (–13.9% and –22.5% versus –7.4%; $P < 0.01$). Significant improvements in HDL cholesterol, triglycerides, apolipoprotein B, lipoprotein(a) and total to HDL cholesterol ratio were also observed. Niacin treatment was generally well tolerated, with □ 60% of patients reporting flushing (> 90% of whom described the flushing as mild or moderate in intensity) and only 7.5% discontinuing due to the flushing (Ballantyne et al 2008). The OCEANS study (**O**pen-label evaluation of the safety and efficacy of a **C**ombination of niacin **E**R and simv**A**statin in patie**N**ts with dy**S**lipidaemia) also evaluated the safety and efficacy of a combination of extended release niacin (2000 mg/day) and simvastatin (40 mg/day) over 52 weeks in 520 patients with mixed dyslipidaemia. At 24 weeks, improvements in non-HDL cholesterol (–27.3%), LDL cholesterol (–25.0%), HDL cholesterol (+23.9%), and triglycerides (–35.9%) (all $P < 0.0001$ vs baseline) were reported. Once again the treatment was generally well tolerated: 71% of patients experienced flushing, of whom 92% were rated as mild or moderate in intensity. In those who experienced flushing, the effects decreased over time, with < 40% reporting flushing during the final 12 weeks of the trial and only 7% discontinuing the trial because of flushing. The combination appears to be both effective and well tolerated in achieving therapeutic lipid goals (Karas et al 2008).

Lovastatin plus extended-release niacin have also been investigated and found to be comparable to atorvastatin and more effective than simvastatin in reducing LDL cholesterol, more effective in increasing HDL cholesterol and to provide greater global improvements in non-HDL cholesterol, triglycerides, and lipoprotein(a) (Bays et al 2003). The combination is associated with good compliance and safety (Rubenfire 2004) and may also be less costly than simvastatin (Armstrong et al 2004).

In a clinical trial of diabetic patients, the addition of niacin 500 mg three times daily to pravastatin 20 mg resulted in a significant lowering of LDL cholesterol compared with pravastatin monotherapy. Furthermore, improvements in lipid profile were gained without compromising glycaemic control (Gardner et al 1997). In a separate trial of simvastatin plus niacin among people with diabetes, glycaemic control initially declined mildly but returned to pretreatment levels at 8 months and remained stable for the remainder of the study (Zhao et al 2004).

As early studies indicated a potential for myopathy, rhabdomyolysis and hepatotoxicity, use of the sustained-release form of niacin in combination with statins is controversial. Although current trials tend to focus on the safer extended-release form, liver function should be monitored and patients observed for symptoms of myopathy (Guyton & Capuzzi 1998).

Low-dose niacin therapy (50 mg twice daily) in combination with statins for 3 months may also significantly increase HDL cholesterol, while avoiding the side effects commonly associated with higher doses (Wink et al 2002).

Diabetes

In people with diabetes, the extended-release niacin may be useful in treating diabetic dyslipidaemia (Pan et al 2002); however, research has indicated the possibility of impaired glucose regulation in patients with type 2 diabetes. In practice this may not be clinically significant (Gardner et al 1997, Guyton 2004, Meyers et al 2004, Zhao et al 2004), and the potential benefits of improved lipid control in diabetic patients for whom other lipid-lowering medications provide inadequate control may outweigh any concerns. Nevertheless, hypoglycaemic medications may need to be monitored and adjusted if necessary (Fonseca 2003).

OTHER USES

Metabolic syndrome

Metabolic syndrome, also known as syndrome X or insulin-resistance syndrome, is a highly prevalent condition that significantly increases the risk of coronary heart disease and is associated with elevated triglycerides, low HDL cholesterol and LDL cholesterol. As niacin raises HDL cholesterol, lowers triglycerides and increases LDL cholesterol particle size, it may be considered a useful therapeutic option for the treatment of dyslipidaemia in such cases (Ito 2004). The potential for niacin to negatively affect glucose metabolism and insulin resistance has led to concerns about its use in practice; however, a recent 3-year trial using niacin plus simvastatin suggests that as long as careful attention is paid to glycaemic control the benefits of niacin appear to outweigh the deleterious effects (Vittone et al 2007).

Preventing diabetes

Nicotinamide has been proposed as a useful therapeutic agent for the prevention of type 1 diabetes and also as an adjunct to intensive insulin therapy (Pocoit et al 1996). Interestingly, nicotinamide has also been shown to cause insulin resistance, resulting in increased insulin secretion in healthy subjects with a family history of type 1 diabetes (Greenbaum et al 1996). A concern therefore exists that monitoring such people for signs of development of the disease may be complicated by the use of nicotinamide.

Protects beta cells

Type 1 diabetes is characterised by progressive beta cell destruction, which leads to complete insulin deficiency; at the time of diagnosis, 80–90% of beta cells have been destroyed (Virtanen & Aro 1994). Nicotinamide has been shown to protect beta cells from inflammatory insults and to improve residual beta-cell function in patients after onset of type 1 diabetes (Gale 1996, Lampeter et al 1998).

One RCT using 25 mg/kg versus 50 mg/kg nicotinamide in early-onset type 1 diabetes (< 4 weeks) found that both doses were likely to be effective in reducing beta-cell dysfunction. As a higher dose may cause insulin resistance, the lower dose is probably preferable (Visalli et al 1999).

Alternatively, another RCT that used slow-release nicotinamide failed to detect a reduction in diabetes incidence after 3 years (Lampeter et al 1998).

Osteoarthritis

As the generation of IL-1 in the synovium and subsequent induction of nitric oxide (NO) synthase is crucial to the pathogenesis of osteoarthritis, the ability of niacinamide to suppress cytokine-mediated induction of NO synthase in a number of types of cells (McCarty & Russell 1999) provides a theoretical basis for its use in the prevention of this condition.

Positive results obtained by a randomised, double-blind, placebo-controlled trial support this theory. In the study, 72 patients with osteoarthritis were treated over 12 weeks with niacinamide or a placebo; active treatment improved the global impact of osteoarthritis, enhancing joint flexibility, reducing inflammation and allowing for reduction in standard anti-inflammatory medications (Jonas et al 1996).

Cancer prevention

Because niacin is required for genomic stability and a deficiency is associated with an increased risk of certain tumours, it has been suggested that niacin may reduce the risk of various cancers (Hageman & Stierum 2001).

Migraine

A systematic review concluded that niacin may have beneficial effects on migraine and tension-type headaches (Prousky & Seely 2005). The effects may be mediated by vasodilation, improved mitochondrial energy metabolism or the correction of low plasma levels of serotonin, which have been implicated in migraine pathogenesis. Niacin may act as a negative feedback regulator to shunt tryptophan into the serotonin pathway, thus increasing plasma serotonin levels (Velling et al 2003).

Alzheimer's dementia

Dementia can be caused by severe niacin deficiency and a prospective study of 6158 people aged > 65 years found that dietary niacin intake (as determined by a food-frequency questionnaire) had a protective effect on the development of Alzheimer's dementia and cognitive decline (Morris et al 2004).

Other conditions

Experimental and clinical studies have suggested that niacin and nicotinamide have potential benefits in reducing hyperphosphataemia in dialysis patients; however, further rigorous trials are required to confirm safety and efficacy (Berns 2008). Although substantial evidence is so far lacking, niacin has also been proposed as a treatment for

Clinical note — Patients with schizophrenia rarely experience skin-flushing side effect

The relative absence of skin flushing in response to niacin supplementation by patients with schizophrenia (80% versus 20%) has been attributed to a reduced pharmacological sensitivity rather than an inadequate cutaneous vasodilatory response. As the skin flush response is prostaglandin-mediated, schizophrenia may be associated with essential fatty acid deficiency or abnormalities in enzymes, receptors or signal transduction mechanisms that affect the synthesis, release or response to vasodilatory PG (Messamore 2003, Messamore et al 2003, Tavares et al 2003). The diminished response is more evident with increasing age, male gender and in the early stages of the disease (Smesny et al 2004, 2005). Diminished sensitivity to niacin skin tests in early psychosis may predict the severity of symptoms (Smesny et al 2003, 2005).

Clinical note — Differences between major forms of niacin supplements

Three main forms of niacin supplements are produced, each with their own set of safety issues. Immediate-release niacin is associated with increased incidence of flushing and other adverse reactions, whereas sustained-release forms have been associated with potential liver damage (Henkin et al 1990, McKenney 2004). In comparison, extended-release niacin has been found to have similar efficacy to immediate-release forms but results in minimal flushing, myopathy or hepatotoxicity (Guyton 2004, McKenney 2004, Pieper 2002, Yim & Chong 2003). Current evidence suggests that the extended-release formulation of niacin has a significantly better safety profile than other niacin formulations and compares favourably with other commonly used lipid-lowering medications. The safety of combined statin and extended-release niacin (niacin-ER) is comparable with the safety of each of the drugs alone (Alsheikh-Ali & Karas 2008).

No-flush preparations of OTC niacin contain no free nicotinic acid and are unlikely to be effective in treating dyslipidaemia (Meyers et al 2003).

psoriasis (Tang et al 2008), intermittent claudication, Raynaud's syndrome and hypothyroidism.

DOSAGE RANGE

Australian RDI

- Women: 11 mg/day.
- Men: 12 mg/day.

Administration with food maximises bioavailability and minimises GI intolerance.

High blood cholesterol and triglyceride levels

- 1500–2000 mg pure crystalline niacin (nicotinic acid) daily — this level should be reached gradually over a period of 4–6 weeks.
- 1500–2000 mg taken once daily for extended-release preparations (best taken at night).
- Inositol hexaniacinate is often associated with less flushing (Rakel 2003).

ADVERSE REACTIONS

Flushing is a common side effect of niacin therapy and may lead to discontinuation of therapy in some individuals (Rubenfire 2004). Night-time administration of extended-release niacin appears to reduce this effect, as does concurrent administration of aspirin (Mills et al 2003, White Robinson et al 2000).

Niacin has been associated with palpitations, worsening of diabetes control, exacerbation of peptic ulcer disease, gout, hepatitis (Crouse 1996), chills, generalised pruritus, gastrointestinal upset, and cutaneous tingling (Mills et al 2003). A case report also exists of increased intraocular pressure in a 73-year-old man with a history of primary open-angle glaucoma taking 500 mg of oral niacin; each time the niacin was withdrawn, the intraocular pressure returned to original levels (Tittler et al 2008).

Reports of hepatotoxicity resulting from sustained-release niacin supplementation appear to be idiosyncratic, as there is no evidence to suggest intrinsic hepatotoxic activity; this also appears to be the case for statins (Parra & Reddy 2003).

SIGNIFICANT INTERACTIONS

Antiretroviral therapy

Extended-release niacin may improve the dyslipidaemia associated with antiretroviral therapy and is considered a safe and effective therapeutic option (Gerber et al 2004). Beneficial interaction is possible.

Diabetes medications

Niacin may affect glycaemic control and increase fasting blood-glucose levels. Therefore medication doses may need to be reviewed: exercise caution and monitor drug requirements when prescribing diabetes medications concurrently with niacin.

Hypolipidaemic agents

Several clinical studies confirm the lipid-lowering effects of vitamin B_3. Although a beneficial interaction has been shown in clinical trials with statin drugs, similar additive effects are theoretically possible with other hypolipidaemic drugs. Beneficial interaction is possible.

Imipramine

A combination of imipramine with L-tryptophan 6 g/day and niacinamide 1500 mg/day has been shown to be more effective for people with bipolar disorder than imipramine alone (Chouinard et al 1979). Beneficial interaction possible.

Isoniazid

Prolonged isoniazid therapy (the drug replaces niacinamide in NAD) may induce pellagra (Beers & Berkow 2003). Increased vitamin B_3 intake may be required with long-term therapy. Beneficial interaction is possible.

Oral contraceptive pill

Use of the oral contraceptive pill may reduce vitamin B_3 levels (Lininger 1999). Increased vitamin B_3 intake may be required with long-term therapy. Beneficial interaction is possible.

Statin drugs (HMG-CoA reductase inhibitors)

The combined use of niacin and statins, including atorvastatin (Lipitor), fluvastatin (Lescol), lovastatin (Mevacor), pravastatin (Pravachol) and simvastatin (Zocor), has been found to provide added therapeutic effects and reduce requirements for statin medications (Ballantyne et al 2008, Karas et al 2008, Gardner et al 1996, 1997, Jacobson et al 1994, Yim & Chong 2003). The addition of niacin may enhance or improve the lipid profile of those who require a further decrease of triglycerides and/or LDL cholesterol and/or increase of HDL cholesterol, even after stable statin therapy.

It should be noted that drug label warnings of an increased risk of adverse events with combined

statin and niacin therapy have been based solely on case reports and are not supported by the scientific literature (Alsheikh-Ali & Karas 2007). Beneficial interaction is possible.

As early studies using the sustained-release form of niacin in combination with lovastatin indicated a potential for myopathy, rhabdomyolysis and hepatotoxicity, use of this form is controversial. Liver function should be monitored and patients observed for symptoms of myopathy (Guyton & Capuzzi 1998). Use sustained-release niacin with caution.

Tamoxifen

The addition of niacin, riboflavin and coenzyme Q10 to tamoxifen therapy may improve mitochondrial antioxidant status and antitumour activity (Perumal et al 2005). The exact role of niacin is unclear; however, the addition of antioxidants to tamoxifen therapy may prove advantageous. Beneficial interaction is possible.

CONTRAINDICATIONS AND PRECAUTIONS

Supplemental vitamin B_3 should be used with caution in conditions involving insulin resistance, although the potential benefits may outweigh the slight increase in blood glucose. In such cases, medication requirements may need to be revised.

As early studies indicated a potential for myopathy, rhabdomyolysis and hepatotoxicity, use of the sustained-release form of niacin in combination with statins is controversial. Liver function should be monitored and patients observed for symptoms of myopathy (Guyton & Capuzzi 1998).

Gout

Excess supplementation can lead to increased production or crystallisation of uric acid (Rakel 2003).

Glaucoma

A case report exists of increased intraocular pressure in a 73-year-old man with a history of primary open-angle glaucoma taking 500 mg of oral niacin; each time the niacin was withdrawn, the intraocular pressure returned to original levels (Tittler et al 2008). Intraocular pressure should be monitored in patients at risk of glaucoma while taking niacin.

Drug screening

Severe adverse reactions (including hepatotoxicity, profound neutrophilia, QT(C)-interval prolongation, metabolic acidosis, nausea, vomiting, dizziness, skin reactions and hypoglycaemia evolving into hyperglycaemia) have been reported in people using high doses of niacin in the misguided belief that it will increase drug clearance and interfere with urine drug screening. Healthcare providers and drug screeners need to be alert to these potentially serious effects (Mittal et al 2007).

PREGNANCY USE

Nicotinic acid is classified as a category B2 medicine in pregnancy by the Australian Drug Evaluation Committee. This means that it has been taken by a limited number of pregnant women and women of childbearing age without any increase in malformations or other direct or indirect harmful effects on the human fetus having been observed.

PRACTICE POINTS/PATIENT COUNSELLING

- The term niacin is used interchangeably with nicotinic acid, and is also used collectively to include nicotinamide (or niacinamide), the amide form of nicotinic acid.
- In practice, nicotinic acid decreases the incidence of secondary myocardial infarction and reduces total mortality incidence in these patients.
- Large doses of niacin reduce total cholesterol, LDL cholesterol, triglycerides and lipoprotein(a) levels, and also markedly raise HDL cholesterol levels.
- The extended-release form appears to have a better safety profile, with reduced incidence of flushing.
- In high doses, it can impair glucose regulation, resulting in insulin resistance, increased insulin secretion and increased fasting blood glucose in patients with type 2 diabetes; care is therefore advised when using the supplement in this group of patients. Alternatively, nicotinamide protects beta cells from inflator damage and may improve residual beta-cell function in patients after onset of type 1 diabetes.

PATIENTS' FAQs

What will this vitamin do for me?

Niacin in high doses will favourably alter lipid levels and reduce the risk of cardiovascular disease, risk of heart attack and risk of death after heart attack. It may also be useful in diabetes when administered under professional supervision.

When will it start to work?

Beneficial effects on lipid levels have been seen within 4 weeks; however, several months of use may be required for optimal effects.

Are there any safety issues?

Several different forms of niacin supplements are produced; however, the extended-release form appears to have a better safety profile than the others and a reduced risk of flushing.

Vitamin B_5 — pantothenic acid

BACKGROUND AND RELEVANT PHARMACOKINETICS

The Greek word *pantos* means 'everywhere'. As the name pantothenic acid implies, it is widely distributed and present in nearly all plant and animal foods. Sensitive to heat and both acid and alkali, considerable amounts are lost through the milling of cereal grains. The intestine is exposed to two sources of pantothenic acid: dietary and bacterial. Current research suggests that bacterial synthesis may be more dominant and important in ruminant species (Bates 1998). Approximately 50% of pantothenic acid is absorbed in the jejunum, an amount that decreases when doses 10-fold greater than the RDI are taken (Groff & Gropper 2009).

The organ with the highest concentration of pantothenic acid is the liver, followed by the adrenal cortex, which reflects the large requirements of these tissues and is indicative of the biochemical role of the vitamin's coenzyme derivatives. There are contrasting opinions about whether a genuine storage capacity exists for this vitamin; however, if there is any at all, the consensus is that pantothenic acid is 'stored' in very limited amounts and in those tissues with the greatest requirements (Groff & Gropper 2009).

Study of placental tissue demonstrates that biotin uses the same transport mechanisms as pantothenic acid, which may indicate competition between these two nutrients in other tissues (Bates 1998).

CHEMICAL COMPONENTS

Pantothenic acid is an amide and consists of B-alanine and pantoic acid joined by a peptide bond. In supplements, it is often found as calcium pantothenate.

FOOD SOURCES

The most concentrated sources are meats (especially liver), egg yolk, broad beans and legumes, but it is also found in many other foods such as whole grains, milk, peanuts, broccoli, avocado, mushroom and apricots. Up to 50% can be lost through cooking (Wahlqvist et al 2002).

Approximately 85% occurs in food as a component of coenzyme A (CoA), which is hydrolysed to pantothenic acid or pantethine during digestion.

DEFICIENCY SIGNS AND SYMPTOMS

Because pantothenic acid deficiency is so rare, most information regarding its signs and symptoms comes from experimental research in animals or cases of severe malnutrition. The deficiency picture appears to be generalised and species-specific (Bates 1998). Preliminary studies in humans using competitive analogues of pantothenic acid have produced the following symptoms:

- 'burning feet syndrome': this affects the lower legs and is characterised by sensation of heat
- cardiac instability
- gastrointestinal disturbance
- dizziness, paraesthesia and depression
- loss of immune (antibody) function
- insensitivity to adrenocorticotrophic hormone
- increased sensitivity to insulin
- vomiting
- fatigue
- weakness.

Some conditions that have been associated with increased requirements are:

- alcoholism (due to typically low intakes of vitamin B complex)
- diabetes mellitus (as a result of increased excretion)
- inflammatory bowel diseases (due to decreased vitamin absorption).

MAIN ACTIONS

Pantothenic acid is involved in myriad important chemical reactions in the body as a result of its involvement in CoA synthesis.

Coenzyme function

CoA and the krebs cycle

Pantothenic acid is required for CoA synthesis and cellular respiration, and plays a pivotal role in the oxidation of fatty acids and acetylation of other molecules, so as to enable transportation. Together with thiamine, riboflavin and niacin, it is involved in the oxidative decarboxylation of pyruvate and alpha-ketoglutarate in the Krebs cycle and ultimately is important for energy storage as well as release.

Acyl carrier protein

Pantothenic acid is the prosthetic group for acyl carrier protein and therefore is involved in the synthesis of fatty acids.

Indirect antioxidant effects

New in vitro research supports an indirect antioxidant role for pantothenic acid through its ability to increase cellular adenosine triphosphate (ATP), which in turn creates increased levels of free glutathione and enhanced protection of cells against peroxidative damage (Slyshenkov et al 2004).

Other functions

It is involved in the synthesis of amino acids, sterols (e.g. cholesterol) and vitamin D. It is necessary for production of the neurotransmitter acetylcholine and the formation of red cells. Vitamin B_5 plays an important role in adrenal function and, as CoA, is needed for proper adrenal cortex function and the synthesis of steroid hormones.

Lipid-lowering

Pantethine, a metabolite of pantothenic acid, has been investigated in several clinical studies and found to exert significant lipid-lowering activity (Coronel et al 1991, Donati et al 1986, Gaddi et al 1984).

The mechanism of action relates to reduced insulin resistance and activation of lipolysis in serum and adipose tissue, according to in vivo research (Naruta & Buko 2001). Additionally, inhibition of HMG-CoA reductase, as well as more distal enzymes in the cholesterol synthetic pathway, are likely to be responsible (McCarty 2001). More recently, an in vitro study demonstrated that pantethine produced a 50% inhibition of fatty acid synthesis and an 80% inhibition of cholesterol synthesis (McRae 2005).

Wound healing

Both oral and topical administration have been shown to accelerate closure of wounds and increase strength of scar tissue in vivo (Plesofsky 2002, Vaxman et al 1990). Both in vitro and in vivo studies reveal that topical dexpanthenol induces activation of fibroblast proliferation, which contributes to accelerated re-epithelialisation in wound healing (Ebner et al 2002).

CLINICAL USE

Although pantothenic acid has been investigated in some studies, most investigation has occurred with several of its derivatives, chiefly an alcoholic analogue of pantothenic acid called dexpanthenol (Bepanthen, see below) and pantethine.

Deficiency states: prevention and treatment

Traditionally, pantothenic acid is recommended together with other vitamin B complex nutrients to treat general deficiency or prevent deficiency in conditions such as alcoholism, diabetes mellitus and malabsorption syndromes.

Enhances wound healing

Pantothenic acid has been both used as an oral supplement and applied topically in a cream base to enhance wound healing; it has been shown to accelerate closure of wounds and increase strength of scar tissue in experimental animals (Plesofsky 2002, Vaxman et al 1990). Although these results are encouraging, there has been little investigation in humans. One double-blind study testing the effects of vitamin C (1000 mg) and pantothenic acid (200 mg) supplements over a 21-day period showed no significant alteration to wound healing with this treatment regimen (Vaxman et al 1995).

Topical use

Bepanthen is a well-known dermatological preparation containing dexpanthenol, an alcoholic analogue of pantothenic acid. It has been investigated in numerous studies and found to act like a moisturiser, activate fibroblast proliferation, accelerate re-epithelialisation in wound healing, have anti-inflammatory activity against UV-induced erythema and reduce itch (Ebner et al 2002). Under double-blind study conditions, epidermal wounds treated with dexpanthenol emulsion showed a reduction in erythema, and more elastic and solid tissue regeneration. Another randomised, prospective, double-blind, placebo-controlled study published in 2003 investigated the efficacy of topical dexpanthenol as a protectant against skin irritation. The study involved 25 healthy volunteers who were treated with a topical preparation containing 5% dexpanthenol or a placebo and then exposed to sodium lauryl sulphate 2% twice daily over 26 days. Treatment with topical dexpanthenol provided protection against skin irritation, whereas a statistically significant deterioration was observed in the placebo group (Biro et al 2003).

Although Bepanthen is commonly used in radiotherapy departments to ameliorate acute radiotherapy skin reactions, a prospective study of 86 patients undergoing radiotherapy showed that topical use of Bepanthen did not improve skin reactions under these conditions (Lokkevik et al 1996). Similarly, negative results were also obtained in an animal study by Dorr et al (2005).

Nasal spray

A RCT of 48 outpatients diagnosed with rhinitis sicca anterior found that dexpanthenol nasal spray is an effective symptomatic treatment for this condition (Kehrl & Sonnemann 1998). Two years later, another RCT compared the effects of xylometazoline-dexpanthenol nasal spray versus xylometazoline nasal spray over a 2-week period in 61 patients with rhinitis after nasal surgery (Kehrl & Sonnemann 2000); it showed that the combination of xylometazoline-dexpanthenol nasal spray was significantly superior to the other treatment and well tolerated.

More recent studies support this emerging trend and point towards a reduction in ciliary and cytotoxic effects from the nasal decongestants when 5% dexpanthenol is concurrently administered (Klocker et al 2003).

Elevated cholesterol and triglyceride levels

Several clinical studies confirm that pantethine, a metabolite of pantothenic acid, exerts significant lipid-lowering activity (Coronel et al 1991, Donati et al 1986, Gaddi et al 1984).

One double-blind study of 29 patients found that 300 mg of pantethine taken three times daily resulted

Clinical note — Could pantothenic acid be an anti-ageing nutrient?

A contemporary theory of ageing implicates mitochondrial functional decline, or 'oxidative decay' of the mitochondria, as a major contributor. In light of this hypothesis, nutrients that possess a critical role in the mitochondria are being re-examined to determine their ability to prevent ageing in humans. The focus has been on pantothenic acid, biotin, lipoic acid, iron and zinc, because deficiencies of these micronutrients have been implicated in increased mitochondrial oxidation (Ames et al 2005, Atamna 2004). In addition, those with antioxidant capabilities are of particular interest, such as pantothenic acid, lipoic acid and zinc.

Because of the numerous nutrients implicated in mitochondrial health and disease, a broad-based multivitamin should be considered instead of a single-nutrient supplement for populations at increased risk of poor nutrition, such as the elderly, young, poor and obese (Ames et al 2005).

in significant reductions to plasma total cholesterol, LDL cholesterol and triglycerides, and an increase in HDL cholesterol levels (Gaddi et al 1984).

A 2005 review analysed results from 28 clinical trials encompassing a pooled population of 646 hyperlipidaemic patients who were supplemented with a mean dose of 900 mg pantethine over an average trial length of 12.7 weeks. The results of these studies suggest a response to pantethine that is time-dependent, with progressively greater reductions in LDL cholesterol and triacylglycerols between month 1 and 9. The most impressive results were observed at 9 months, with a reduction of total cholesterol by 20.5%, LDL cholesterol by 27.6% and triacylglycerols by 36.5% from baseline. Although minor increases were observed in HDL levels in the early stages of most trials, longer-term studies suggested that this is not sustained.

Of the trials studied, 22 were conducted in Italy and all were conducted between 1981 and 1991. The authors point out that no further clinical trials were published, and concluded that evidence to date has yielded positive and promising results, and further research is warranted.

OTHER USES

Pantothenic acid has been used for many other indications, but controlled studies to determine whether treatment is effective are lacking.

Stress

As vitamin B_5 is essential for adrenal cortex function and the synthesis of steroid hormones, it is often used together with other B vitamins during times of stress in order to improve the body's response and restore nutrient levels. Interestingly, a large number of experiments in the 1950s attempted to elicit the impact of pantothenic acid deficiency on adrenal function and stress response in animals; however, little research has been done since. A small study demonstrated that injections of pantothenic acid in B_5-deficient rats corrected the deficiency and had a steroidogenous effect.

Inflammatory conditions

Pantothenic acid has been used as adjunctive treatment in inflammatory conditions such as asthma and dermatitis, with the intention of improving adrenal cortex output of hormones that have anti-inflammatory activity.

Clinical note — Could Vitamin B_5 prevent neural tube defects?

Ongoing evidence from animal studies suggests that pantothenic acid may have a preventative role against neural tube defects (NTDs) independent of folic acid (Dawson et al 2006). Pharmaceuticals such as valproic acid that increase the risk of NTD offspring have been shown also to reduce hepatic concentrations of CoA, an effect attenuated by co-administration of pantothenic acid. While the role of B_5 in neural tube closure remains unknown, it appears that it exerts actions both overlapping with and independent of folate.

Ergogenic aid

Based on its role in carbohydrate metabolism, vitamin B_5 has been used to increase stamina and athletic performance.

Reducing drug toxicity

Preliminary research in animal models shows that pantothenic acid reduces the toxicity effects of kanamycin and carbon tetrachloride and, when combined with carnitine, protects against valproate toxicity (Moiseenok et al 1984, Nagiel-Ostaszewski & Lau-Cam 1990, Thurston & Hauhart 1992).

Female alopecia

According to a study of 46 women with symptoms of diffuse alopecia, calcium pantothenate (200 mg/day) over 4–5 months does not cause a significant improvement in this condition (Brzezinska-Wcislo 2001).

DOSAGE RANGE

Australian ADI

- Women: 4 mg/day.
- Men: 6 mg/day.

According to clinical studies

- Wound healing: dexpanthenol cream 5% applied to affected areas up to two times daily.
- Lipid-lowering: pantethine 300 mg three times daily.

TOXICITY

No toxicity level known.

ADVERSE REACTIONS

Pantothenic acid is well tolerated, but contact dermatitis has been reported with topical dexpanthenol.

SIGNIFICANT INTERACTIONS

Antibiotics

Antibiotics will reduce endogenous production of vitamin B_5 by gastrointestinal flora. Increase vitamin B_5-rich foods or consider supplementation.

Oral contraceptive pill

Taking the OCP may increase the requirement for pantothenic acid. Increase vitamin B_5 rich foods or consider supplementation (Plesofsky 2002).

CONTRAINDICATIONS AND PRECAUTIONS

None known.

PREGNANCY USE

Considered safe when ingested at usual dietary doses.

PATIENTS' FAQs

What will this vitamin do for me?

Vitamin B_5 is essential for health and is used for many different conditions; for example, it is often used as part of a vitamin B complex supplement to aid the body during times of stress. In many of its uses research is not available to determine whether it is effective. Research generally supports its use in wound healing and in the form of pantethine to reduce cholesterol levels.

When will it start to work?
Pantethine reduces cholesterol levels within 2 months; however, optimal results are achieved with 9 months of supplementation. Xylometazoline-dexpanthenol nasal spray reduces symptoms of rhinitis within 2 weeks. It is not known how quickly the vitamin starts to work in most other conditions.

Are there any safety issues?
Pantothenic acid and pantethine are considered safe substances and are generally well tolerated.

PRACTICE POINTS/PATIENT COUNSELLING

- Deficiency is extremely rare, as pantothenic acid is widely distributed and present in nearly all plant and animal foods. Those at risk of reduced vitamin status are alcoholics, diabetics and people with malabsorption syndromes.
- Pantethine reduces total cholesterol levels significantly, according to controlled studies in both healthy and diabetic people.
- Dexpanthenol cream acts like a moisturiser, activates fibroblast proliferation, accelerates re-epithelialisation in wound healing, has anti-inflammatory activity against UV-induced erythema and reduces itch. When used in a nasal spray, it reduces symptoms of rhinitis.
- Vitamin B_5 supplements are commonly used together with other B vitamins during times of stress in order to improve the body's response and restore nutrient levels.
- Vitamin B_5 has also been used as adjunctive treatment for inflammatory conditions such as dermatitis and asthma, as an ergogenic aid, to treat alopecia and to restore colour to greying hair, although no controlled studies are available to determine effectiveness in these conditions.

Vitamin B_6

BACKGROUND AND RELEVANT PHARMACOKINETICS

Vitamin B_6 was discovered in 1938. Absorption of vitamin B_6, also known as pyridoxine, takes place in the jejunum by a passive, non-saturable process. The more acidic the environment, the greater is the absorption. It is transported in the plasma and red blood cells to the liver, where it is converted to pyridoxal 5′ -phosphate, and is then available to other tissues. It is mainly stored in muscle tissue, and ultimately metabolised and excreted via the kidneys.

CHEMICAL COMPONENTS

Vitamin B_6 is a water-soluble vitamin and has six forms, of which pyridoxine hydrochloride is the main form found in supplements and used to fortify foods. Pyridoxine is the alcohol form, pyridoxal the aldehydic form and pyridoxamine the amine form. Each has a 5′-phosphate derivative.

FOOD SOURCES

Vitamin B_6 is widely distributed in animal and plant foods. The best food sources are fish, organ meats, legumes, wheatgerm, eggs, nuts, potatoes and bananas. Per milligram, Vegemite is one of the richest sources.

Up to 40% can be lost through cooking (Wahlqvist et al 1997).

DEFICIENCY SIGNS AND SYMPTOMS

Clinical signs and symptoms are non-specific because this vitamin is necessary for the proper functioning of over 60 enzymes (Pelton et al 2000, Wahlqvist et al 1997). In adults with B_6 deficiency, chiefly dermatological, circulatory and neurological changes develop. In children, the central nervous system is also affected.

- dermatitis (similar to that seen in pellagra)
- angular stomatitis and glossitis, and cheilosis
- sideroblastic anaemia
- impaired antibody production
- renal calculi
- elevated homocysteine levels (Lakshmi & Ramalakshmi 1998)
- CNS effects such as irritability, confusion, lethargy, clinical depression, elevated seizure activity (particularly in children), abnormal brain wave patterns and nerve conduction
- birth defects such as cleft palate (associated with elevated homocysteine) (Weingaertner et al 2005)

Pyridoxine deficiency has also been associated with premature coronary artery disease and with impaired oxidative defence mechanisms (Miner et al 2001).

Primary deficiency

Primary deficiency is rare because this vitamin is widely available in many foods. Groups at risk of deficiency include breastfed babies born with low plasma B_6 levels, the elderly, people who consume large quantities of alcohol and people on dialysis due to abnormal vitamin loss (Groff & Gropper 2009).

Secondary deficiency

This may result from malabsorption syndromes, cancer, liver cirrhosis and alcoholism, hyperthyroidism, congestive heart failure or medicine use (such as the oral contraceptive pill), isoniazid, hydralazine, penicillamine, theophylline or monoamine oxidase (MAO) inhibitors (Beers & Berkow 2003, Bratman & Kroll 2000, Wardlaw 1997).

MAIN ACTIONS

Coenzyme

Vitamin B_6 is an important coenzyme in the biosynthesis of the neurotransmitters GABA, dopamine and serotonin (Gerster 1996). It is also involved in protein metabolism, haemoglobin synthesis, gluconeogenesis, lipid metabolism, niacin formation, immune system processes, nucleic acid synthesis and hormone modulation (Bratman & Kroll 2000, Wardlaw 1997).

Clinical note — Marginal B_6 deficiency

Although frank deficiency is rare, marginal deficiency appears to be common. One study found that 100% of 174 university students tested had some degree of vitamin B_6 deficiency (Shizukuishi et al 1981). A larger survey of 11,658 adults found that 71% of males and 90% of females did not meet the RDI requirements for B_6 (Kant & Block 1990).

Homocysteine

Homocysteine is formed from the essential amino acid methionine and about 50% is then remethylated to methionine via steps that require folic acid and vitamin B_{12}. Vitamin B_6 is required for another metabolic pathway and is a cofactor for cystathionine beta-synthase, which mediates the transformation of homocysteine to cystathionine (Wilcken & Wilcken 1998).

Serotonin

Pyridoxine is required for the synthesis of many neurotransmitters, including serotonin. It is a cofactor for the enzyme 5-hydroxytryptophan decarboxylase, which is involved in one of the steps that converts tryptophan to serotonin (Pelton et al 2000). Deficiency states are therefore associated with alterations to mood and other psychological disturbances.

Antioxidant

B_6 has been shown both in vitro and in vivo to display antioxidant activity (Kannan & Jain 2004, Anand 2005, Ji et al 2006, Matxain et al 2007).

Antitumour

In vitro and in vivo experiments have found evidence of some antitumour action on a number of cell lines, including breast and pituitary cells (Shimada et al 2005, Ren & Melmed 2006, Shimada et al 2006).

Reducing diabetic complications

According to Jain et al (2007), animal studies show that B_6 may reduce the incidence of several diabetic complications, such as retinopathy, nephropathy and dyslipidaemia. It is thought that advanced glycation end-products (AGEs) contribute to the development of diabetic nephropathy and other diabetes complications, and according to in vivo research, pyridoxamine (from the B_6 group of compounds) exerts antioxidant and anti-AGE action in the kidneys (Tanimoto et al 2007). The anti-AGE action of pyridoxal phosphate was confirmed in a diabetic rat model, where it prevented the progression of nephropathy (Nakamura et al 2007).

OTHER ACTIONS

Pyridoxine displayed a protective effect against neurotoxicity induced by glutamate in vivo, which may prove useful in hypoxic-ischaemic brain injury (Buyukokuroglu et al 2007). Another animal study indicated that neuroprotective activity preventing ischaemic damage may be due to a gamma aminobutyric acid (GABA) inhibitory effect (Hwang et al 2007).

Immune stimulant actions, with an increase in T-helper and T-lymphocyte cells, were found in critically ill patients to whom B_6 was administered (Cheng et al 2006).

CLINICAL USE

Vitamin B_6 supplementation is used to treat a large variety of conditions and is mostly prescribed in combination with other B group vitamins.

Deficiency

It is traditionally used to treat vitamin B_6 deficiency.

Premenstrual syndrome (PMS)

Vitamin B_6 supplementation is used in doses beyond RDI levels for the treatment of PMS. A 1999 systematic review of nine clinical trials involving 940 patients with PMS supports this use, finding that doses up to 100 mg/day are likely to be of benefit in treating symptoms and PMS-related depression (Wyatt et al 1999). Another recent double-blind RCT of 94 patients taking a dose of 40 mg B_6 twice a day found active treatment significantly decreased PMS symptoms during the second cycle. Benefits were most pronounced for mood and psychiatric symptoms (Kashanian et al 2008).

Comparative study

One randomised double-blind study compared the effects of pyridoxine (300 mg/day), alprazolam (0.75 mg/day), fluoxetine (10 mg/day) or propranolol (20 mg/day) in four groups of 30 women with severe PMS (Diegoli et al 1998). In this study, fluoxetine produced the best results (a mean reduction of 65.4% in symptoms), followed by propanolol (58.7%), alprazolam (55.6%), pyridoxine (45.3%) and the placebo (39.4–46.1%). Symptoms responding well to pyridoxine were tachycardia, insomnia, acne and nausea (Diegoli et al 1998). Another comparative study of 60 women tested 100 mg of B_6 against bromocriptine and a placebo over 3 months. Both active treatments produced a significant reduction in symptoms compared to the control group; however, vitamin B_6 treatment was slightly more effective than bromocriptine and produced fewer side effects (Sharma et al 2007).

Morning sickness

A Cochrane Review in 2000 of 23 randomised trials investigating all treatments for morning sickness concluded that pyridoxine significantly reduces the severity of morning sickness (Jewell & Young 2002). More recent research supports this finding. A well designed, double-blind, randomised, controlled trial found 55% of women receiving B_6 supplements experienced a significant subjective improvement in symptoms over a 3-week period compared to the placebo (Smith & Crowther 2005). Other clinical trials comparing B_6 and ginger have concluded that both are effective in reducing nausea in pregnancy (Ensiyeh & Sakineh in press, Chittumma et al 2007).

Heart disease

Elevated homocysteine (Hcy) levels

In practice, the relative safety and affordability of combined vitamin B supplementation (B_{12}, folic acid and B_6) make it an attractive recommendation in people with familial hyperhomocysteinaemia. Whether lowering total Hcy improves cardiovascular mortality and morbidity is questionable, as recent large-scale clinical trials and meta-analyses have failed to demonstrate any benefits for B group vitamins (including B_6) in reducing overall cardiovascular risk, despite showing a reduction in homocysteine levels (Albert et al 2008, Clarke et al 2007, CTSUESU 2006, den Heijer et al 2007, Mann et al 2008, Marcus et al 2007, Ray et al 2007). Failure of combined B vitamin therapy to reverse inflammatory processes associated with atherogenesis may partly explain the negative results (Bleie et al 2007). The consistent findings of an association between elevated plasma total Hcy levels and vascular risk is yet to be fully explained; however, it is possible that the association is a consequence rather than a cause of disease (Toole et al 2004).

Reducing thromboembolism

A prospective cohort study of 757 patients experiencing first venous thromboembolism found that patients with lower plasma B_6 had a 1.8-fold higher risk of recurrence than those with higher levels of B_6 (Hron et al 2007). In contrast, no risk reduction was found in a secondary analysis of (HOPE)-2 trial which included over 5,000 individuals with known cardiovascular disease or diabetes who were given a daily supplement of folic acid (2.5 mg), B_6 (50 mg) and B_{12} (1 mg) or a placebo for 5 years. In this analysis, vitamin therapy reduced Hcy levels; however, it did not reduce the risk of venous thromboembolism, deep vein thrombosis or pulmonary embolism (Ray et al 2007).

Improving outcomes after heart transplantation

Cardiac transplantation represents a potentially life-saving procedure for patients with end-stage cardiac disease. Short-term survival is improving because of improved immunosuppression, but long-term survival remains limited by an aggressive form of atherosclerosis known as transplant coronary artery disease (Miner et al 2001).

A randomised, double-blind placebo-controlled study showed that pyridoxine supplementation (100 mg/day) taken for 10 weeks improved endothelial function as assessed by flow-mediated dilatation in cardiac transplant recipients (Miner et al 2001). Interestingly, homocysteine levels remained unchanged with treatment, suggesting other mechanisms are responsible.

Improving other cardiovascular risk factors

A randomised, double blind, placebo controlled study of 50 patients who were perceived to be at risk of cerebral ischaemia received B_6 (25 mg), folate (2.5 mg) and B_{12} (0.5 mg) or a placebo daily for a year. The study found supplementation significantly reduced carotid intima-media thickness, which is a marker of atherosclerotic changes (Till et al 2005). In contrast, another small, double-blind, randomised and placebo-controlled trial of 30 individuals with a history of ischaemic stroke found that long-term treatment over 3.9 years with similar dosages of B_6 and B_{12} to the previous trial and slightly less folate (2 mg) produced no differences in carotid intima-media thickness and endothelial function (Potter et al 2007).

Bladder cancer

In an attempt to find a link between dietary components and incidence of bladder cancer, diet was assessed for 912 patients with bladder cancer and 873 controls by Garcia-Closas et al (2007). Individuals in the highest quintile for B_6 intake had a 40% reduced risk of bladder cancer compared with those in the lowest quintile.

Colorectal cancer

Current evidence suggests high dietary vitamin B_6 intake is associated with a reduced risk of colorectal cancer. One large longitudinal population study ($n = 61$; 433 women aged 40–76 years) used a food-frequency questionnaire with a follow-up over 14.8 years and found that high dietary vitamin B_6 was associated with lower colorectal cancer risk, with protective effects most notably seen in women who drank alcohol (Larsson et al 2005). Similarly, a case control study of 2,028 people with colorectal cancer and 2,722 controls confirmed a dose-dependent protective effect of B_6, with strongest protective effects observed for the highest intake and in people aged over 55 years (Theodoratou et al 2008). Another large population study of both men and women further confirmed that low dietary B_6 was associated with an increased risk in colorectal cancer, but the effect was specific for men and not for women. Protective effects were strongest in men with higher alcohol intake. These findings were from the large Japan Public Health Center-based Prospective Study, from which there were 526 cases of colorectal cancer (Ishihara et al 2007). An RCT also found that high levels of plasma B_6 may be protective against colorectal adenomas (Figueiredo et al 2008).

Carpal tunnel syndrome

It has been suspected that vitamin B_6 deficiency may play a role in the development of carpal tunnel syndrome (CTS) as several studies have found that patients with CTS and pyridoxine deficiency respond to supplementation (Ellis et al 1991). More recent evidence now casts doubt on the usefulness of B_6 supplementation in CTS. A 2002 review found no benefit with pyridoxine treatment in CTS (Gerritsen et al 2002). Similarly, a 2007 systematic review of treatments for CTS concluded that there was moderately strong evidence to suggest that B_6 was ineffective in the treatment of the condition (Piazzini et al 2007).

Autism

High-dose pyridoxine and magnesium supplementation is a popular nutritional treatment in autism, although current evidence is contradictory. A critical analysis of 12 published studies concluded that evidence generally supports the efficacy of vitamin treatment; however, there were methodological shortcomings inherent in many of the studies (Pfeiffer et al 1995). Other more recent studies also support the use of a combination treatment of magnesium and B_6 for improving symptoms such as social interaction, communication and general behaviour in autism (Mousain-Bosc et al 2006). It is suspected that some autistic individuals may benefit from B_6 supplementation as a result of an impairment of the conversion of pyridoxine and pyridoxal to pyridoxal 5 phosphate (Adams et al 2006).

In contrast, a small, 10-week, double-blind, placebo-controlled trial found that an average dose of 638.9 mg pyridoxine and 216.3 mg magnesium oxide was ineffective in ameliorating autistic behaviours (Findling et al 1997). In 2006, a systematic review found that the quality and small sizes of the studies posed problems in evaluating the evidence that led to their conclusion that B_6-Mg therapy could not be recommended (Nye & Brice 2005).

Convulsions during a febrile episode

Two randomised trials have been conducted in children, producing conflicting results. One study of 65 children who had been admitted to hospital with febrile convulsions showed that a dose of 2–10 mg/kg pyridoxal phosphate daily (PO or IV) produced a 100% success rate, whereas 43% in the control group experienced repeated convulsions (Kamiishi et al 1996). A second randomised trial found that a lower dose of 20 mg twice daily did not alter the incidence of febrile convulsions compared with placebo (McKiernan et al 1981).

Symptomatic treatment for stress

The term 'stress', as used by the public, is a subjective one and often described in different ways. One theoretical model that has been developed to predict psychological stress includes measures of life stressors, social support and coping style. Using this model, pyridoxine deficiency has been identified as a significant predictor of increased overall psychological stress during bereavement. More specifically, pyridoxine deficiency is significantly associated with increases in depression, fatigue and confused mood levels, but not with those of anxiety, anger or vigour (Baldewicz et al 1998).

One explanation is that pyridoxine is involved in neurotransmitter biosynthesis, such as GABA and serotonin, and therefore deficiency states that are associated with mood disturbances are improved with consequent supplementation (McCarty 2000).

Cognitive performance/Alzheimer's disease

Whether vitamin B_6 supplementation provides benefits in cognitive function and Alzheimer's disease (AD) remains to be clarified. It has gained some attention as a cheap and safe method of reducing homocysteine, which is implicated in the aetiology of AD and cognitive dysfunction; however, findings are equivocal.

One systematic review evaluated data from 16 studies that investigated the association between cognitive function in the elderly and B_6, folate and B_{12}. An association was found between folate and cognition in AD, but no association was found for vitamins B_6 or B_{12}. However, the authors suggested that heterogeneity in the methodology of the studies made interpretation problematic (Raman et al 2007).

A similar research group doing a systematic review of 14 trials found that most studies were small and of low quality. They found that three studies of B_6 and six trials of combined B vitamins revealed no effect, despite different dosages, on cognitive function. Only one of the trials found a significant improvement using B_6 to improve long-term memory. The review concluded that there was insufficient evidence to support a positive effect of B_6 on cognition. The reviewers suggested that larger, well designed trials are needed to assess different groups of the population for any association between B_6 and cognitive function (Balk et al 2007).

Homocysteine and AD

According to one systematic review published in 2008, evidence is strong to suggest high homocysteine is a risk factor for AD and further randomised controlled trials are warranted to evaluate the association between B_6, folate, B_{12}, homocysteine levels and AD (Van Dam & Van Gool 2008).

Brain matter

Investigation of a healthy elderly population found a relationship between greater B_6 supplement intake and greater grey matter volume (Erickson et al 2008). Another study with Alzheimer's patients found that low B_6 levels in patients were associated with white matter lesions in the brain (Mulder et al 2005). The clinical significance of these findings remains to be clarified.

It has also been theorised that inflammation may be implicated in AD and dementia and that C-reactive protein (CRP), as a marker for systemic inflammation, may be a risk factor. A study of 85 individuals discovered that, where CRP was elevated, this was related to low B_6 levels and cerebral atrophy (Diaz-Arrastia et al 2006). This anti-inflammatory effect of B_6 may explain its possible role in neurodegenerative diseases; another interesting observation came from a study with older men, where levels of beta amyloid levels were reduced with B_6, folate and B_{12} (Flicker et al 2008).

Schizophrenia

It has been suggested that high levels of homocysteine (Hcy) contribute to the pathogenesis of schizophrenia and the complex metabolic regulation of Hcy that could be disrupted in schizophrenia (Petronijevic et al 2008).

To test whether supplementation could benefit this population, Levine et al (2006) conducted an RCT of 42 schizophrenic patients with plasma Hcy levels > 15 micromol/L. Treatment with oral folic acid, vitamin B_{12} and pyridoxine for 3 months reduced Hcy and, more importantly, significantly improved clinical symptoms as measured by the Positive and Negative Syndrome Scale and neuropsychological tests overall, in particular the Wisconsin Card Sort (Levine et al 2006).

Tardive dyskinesia (TD)

Tardive dyskinesia is a significant clinical problem. Vitamin B_6 is a potent antioxidant and has a role in almost all of the possible mechanisms that are thought to be associated with appearance of TD (Lerner et al 2007). To test whether supplementation would have any benefits, a 26-week, double-blind, placebo-controlled trial was conducted with 50 inpatients who had DSM-IV diagnoses of schizophrenia or schizoaffective disorder and TD. The randomised study found treatment with vitamin B_6 (1200 mg/day) significantly reduced symptoms of TD compared to a placebo.

Parkinson's disease (PD)

A higher dietary intake of vitamin B_6 was associated with a significantly decreased risk of PD, probably through mechanisms unrelated to homocysteine metabolism according to findings from the Rotterdam Study — a prospective, population-based cohort study of people aged 55 years and older (de Lau et al 2006). The association between dietary intake of folate, vitamin B_{12} and vitamin B_6 and the risk of incident PD among 5,289 participants was evaluated. After a mean follow-up of 9.7 years, the authors identified 72 participants with incident PD. Stratified analyses showed that this association was restricted to smokers. No association was observed for dietary folate and vitamin B_{12}.

Hyperhomocysteinaemia has been reported repeatedly in PD patients; the increase, however, seems mostly related to the methylated catabolism of l-Dopa, the main pharmacological treatment of PD (Martignoni et al 2007).

OTHER USES

Vitamin B_6 supplements are effective for treating hereditary sideroblastic anaemia and refractory seizures in newborns, caused by pyridoxine withdrawal after delivery. Vitamin B_6 supplements have been used to prevent diabetic retinopathy and kidney stones, and to treat symptoms of vertigo, allergy to monosodium glutamate, asthma, photosensitivity and pervasive developmental disorders with hypersensitivity to sound. Women taking the oral contraceptive pill sometimes use supplemental B_6 to relieve mood disturbances and restore vitamin status.

A small trial has shown some future potential clinical use in renal transplant patients with high Hcy levels and endothelial dysfunction. A dose of folate (5 mg/day), B_6 (50 mg/day) and B_{12} (1000 microgram/day) was given to stable renal transplant

patients for 6 months and Hcy levels decreased and endothelial function was improved compared to the control patients (Xu et al 2008). Further trials are needed to confirm this finding.

Dream states

Many have suspected that pyridoxine supplements taken at night are able to influence dream states and sleep, causing disruption in some people. The results of a 2002 double-blind, placebo-controlled crossover study support this observation (Ebben et al 2002). Pyridoxine supplementation (250 mg) taken before bedtime was shown to significantly influence dream-salience scores (a composite score containing measures for vividness, bizarreness, emotionality and colour), starting on the first night of treatment.

Leg cramps during pregnancy

A study of 84 pregnant women with leg cramps found that a combination of vitamin B_1 (100 mg/day) and B_6 (40 mg/day) improved symptoms 7.5 fold, and this was a better result than given by treatment with calcium carbonate (Sohrabvand et al 2006).

DOSAGE RANGE

- Prevention of deficiency: Australian RDI for adults and children > 8 years: 1–1.7 mg/day.
- Treatment of deficiency: 5–25 mg/day.
- Morning sickness: 30–75 mg/day, sometimes taken as 25 mg three times daily.
- Symptoms of PMS: 100–500 mg/day.
- Elevated homocysteine levels: 100 mg/day (usually taken with B_{12} and folic acid).
- Leg cramps in pregnancy: vitamin B_1 100 mg/day and B_6 40 mg/day.
- Schizophrenic people with tardive dyskinesia: vitamin B_6 (1200 mg/day).

TOXICITY

Symptoms of toxicity include paraesthesia, hyperaesthesia, bone pain, muscle weakness, numbness and fasciculation, most marked at the extremities (Dalton & Dalton 1987, Diegoli et al 1998). Some symptoms include unsteady gait, numbness of the hands and feet, impaired tendon reflexes. Excessive doses of vitamin B_6 cause degeneration of the dorsal root ganglia in the spinal cord, loss of myelination and degeneration of sensory fibres in the peripheral nerves.

The dose and time frame at which toxicity occurs vary significantly between individuals. Studies involving large population groups using 100–150 mg/day have shown minimal or no toxicity in 5- to 10-year studies, whereas studies of women self-medicating for PMS, taking 117 ± 92 mg for 2.9 ± 1.9 years, have reported increased incidence of peripheral neuropathy (Bernstein 1990, Dalton & Dalton 1987).

ADVERSE REACTIONS

Pyridoxine is considered non-toxic, although nausea and vomiting, headache, paraesthesia, sleepiness and low-serum folic acid levels have been reported.

Supplements taken at night may result in more vivid dreams and, for some individuals, disrupted sleep (Ebben et al 2002).

SIGNIFICANT INTERACTIONS

Amiodarone

Pyridoxine may increase the risk of drug-induced photosensitivity. Exercise caution with patients taking pyridoxine and amiodarone concurrently.

Antibiotics

Destruction of gastrointestinal flora can decrease endogenous production of vitamin B_6. Increase intake of vitamin B_6-rich foods or consider supplementation with long-term drug treatment.

Hydralazine

Hydralazine may induce B_6 deficiency according to a clinical study. Increased intake may be required with long-term drug therapy.

Isoniazid

Isoniazid increases vitamin B_6 requirements. Increase intake of vitamin B_6-rich foods or consider supplementation with long-term drug treatment.

L-Dopa (without carbidopa)

In people with Parkinson's disease, L-dopa can cause hyperhomocysteinaemia, the extent of which is influenced by B-vitamin status. To maintain normal plasma homocysteine concentrations, the B-vitamin requirements are higher in L-dopa-treated patients than in those not on L-dopa therapy. B-vitamin supplements may be warranted for PD patients on L-dopa therapy (Miller et al 2003)

Oral contraceptives

Oral contraceptives increase vitamin B_6 requirements. Increase intake of vitamin B_6-rich foods or consider supplementation with long-term drug treatment.

Penicillamine

This drug increases vitamin B_6 requirements. Increase intake of vitamin B_6-rich foods or consider supplementation.

Phenobarbitone, phenytoin

Vitamin B_6 supplements may lower plasma levels and efficacy of these drugs. Monitor for drug effectiveness, and exercise caution when these drugs are being taken concurrently.

Theophylline

May induce pyridoxine deficiency. Increased intake may be required with long-term drug therapy.

CONTRAINDICATIONS AND PRECAUTIONS

Monitor long-term use of high-dose pyridoxine supplements (> 100 mg, although this level varies between individuals).

PREGNANCY USE

Pyridoxine supplements are commonly used during pregnancy to reduce symptoms of morning sickness, suggesting safety when used in appropriate doses.

PRACTICE POINTS/PATIENT COUNSELLING

- Vitamin B_6 is available in many foods; however, several surveys suggest that inadequate intakes are common.
- Deficiency can manifest with psychological symptoms of depression, irritability and confusion, and physical symptoms of lethargy, dermatitis, angular stomatitis, glossitis and impaired immunity.
- Overall, clinical research supports the use of vitamin B_6 supplements in relieving mild-to-moderate symptoms of PMS (particularly breast tenderness and mood disturbance), nausea in pregnancy and as a treatment for hyperhomocysteinaemia.
- Preliminary evidence suggests regular dietary B_6 in levels above the RDA may have a protective effect in colorectal cancer, bladder cancer risk and incidence of Parkinson's disease.
- There is conflicting evidence as to whether vitamin B_6 supplements improve symptoms of carpal tunnel syndrome and autism (combined with magnesium), and whether they prevent febrile convulsions in children.
- Pyridoxine should not be used in high doses for the long term, as this can induce toxicity.

PATIENTS' FAQs

What will this vitamin do for me?

Vitamin B_6 is essential for the body's normal functioning. It has been used to treat many different conditions; however, scientific evidence generally supports its use in only a few conditions (e.g. morning sickness, mild-to-moderate PMS and elevated homocysteine levels).

When will it start to work?

This will depend on what is being treated. With regard to PMS symptoms, effects may take two to three menstrual cycles, whereas for morning sickness effects can be seen within two to three days.

Are there any safety issues?

High doses should not be taken for the long term, as this can cause toxicity.

Vitamin B_{12}

BACKGROUND AND RELEVANT PHARMACOKINETICS

Vitamin B_{12} (cobalamin) is a water-soluble vitamin obtained mostly from animal protein products in the diet. In the stomach gastric acid is required to liberate protein-bound cobalamin, which is then immediately bound to R-binders (glycoproteins) that protect it from being denatured. When the contents of the stomach reach the duodenum, the R-binders are partially digested by pancreatic proteases, releasing them to bind to intrinsic factor (a glycoprotein), which is secreted by the parietal cells of the gastric mucosa. This complex is then absorbed in the terminal ileum and transported to cells, where it carries out its metabolic function, or to the liver, where it is stored until required (FAO/WHO 2002, Oh & Brown 2003). An alternative method of absorption, which is independent of intrinsic factor, also appears to exist and accounts for the absorption of approximately 1% of large oral doses (> 300 μg) of B_{12} (Elia 1998). Absorption via intrinsic factor is limited to about 1.5–2.0 μg/meal owing to limited receptor capacity (FAO/WHO 2002).

CHEMICAL COMPONENTS

Vitamin B_{12} is the largest of the B vitamins and is a complex structure containing a central cobalt atom. There are five forms of B_{12}: cyanocobalamin (a synthetic form that has a cyanide attached to the cobalt), hydroxycobalamin (hydroxyl group attached to the cobalt; it is produced for parenteral administration), aquacobalamin (water group bound to the cobalt) and the coenzymatically active forms (methylcobalamin and 5-deoxyadenosylcobalamin), in which a methyl group or a 5-deoxyadenosyl group is bound to the cobalt atom (FAO/WHO 2002, Freeman et al 1999).

FOOD SOURCES

Lambs liver, sardines, oysters, egg yolk, fish, beef, kidney, cheese and milk. Up to 10% is lost in cooking (Wahlqvist 2002). Fortified breakfast cereals are also becoming increasingly available.

Vitamin B_{12} bioavailability significantly decreases with increasing intake as the intrinsic factor-mediated intestinal absorption system is estimated to be saturated at about 1.5–2.0 μg/meal for healthy adults with normal gastrointestinal function. The bioavailability of vitamin B_{12} from different sources is variable: fish (42%), lamb (56–89%), chicken (61–66%), eggs (< 9%) (Watanabe 2007).

Plants do not contain B_{12} because they have no cobalamin-dependent enzymes (Croft et al 2005). Most microorganisms, including bacteria and algae, synthesise B_{12}, which then makes its way into the food chain (FAO/WHO 2002). Human intestinal bacteria also synthesise B_{12}, but this is not absorbed to any considerable extent (Wahlqvist 2002). Vegans living in situations with more stringent hygiene are therefore more likely to develop deficiencies.

Clinical note — Nori: a source for vegetarians

Rat studies have demonstrated improvements in B_{12} status following the ingestion of nori (seaweed). Nori is said to contain as much B_{12} as liver (Croft et al 2005) approximately 55–59 μg/100 g dry weight. Five different biologically active vitamin B_{12} compounds have been identified in nori: cyanocobalamin, hydroxycobalamin, sulfitocobalamin, adenosylcobalamin and methylcobalamin (Takenaka et al 2001); the source of B_{12} appears to be bacteria (Croft et al 2005).

DEFICIENCY SIGNS AND SYMPTOMS

Vitamin B_{12} deficiencies manifest primarily as haematological and neurological disturbances, and are estimated to affect 10–15% of individuals over the age of 60 years (Baik & Russell 1999).

- Haemotological: macrocytic (megaloblastic) anaemia, pancytopenia (leukopenia, thrombocytopenia); symptoms may include lethargy, dyspnoea, anorexia, weight loss and pallor (Wahlqvist 2002).
- Neurological disturbances: paraesthesias, optic neuropathy (reversible), peripheral neuropathy and demyelination of the corticospinal tract and dorsal columns (subacute combined systems disease).
- Psychological disturbances: impaired memory, irritability, depression, personality change, dementia and psychosis (Lee 1999, Lindenbaum et al 1988).
- Various gastrointestinal symptoms can also develop, such as loss of appetite, intermittent constipation and diarrhoea, glossitis and abdominal pain.
- Folic acid supplementation may mask an underlying B_{12} deficiency, leading to the progression of neurological symptoms.

Primary deficiency

People at risk are those living in India, Central and South America, and selected areas in Africa (Stabler & Allen 2004), strict vegetarians and vegans, breastfed infants of vegetarian mothers with low B_{12} stores, elderly patients with 'tea and toast diets' and chronic alcoholics. As vitamin B_{12} is stored to a considerable extent, even after complete depletion of food-ingested cobalamin, clinically relevant deficiencies will usually only develop after 5–10 years (Schenk et al 1999). This time frame increases to an average of approximately 18 years in strict vegetarians when intrinsic factor secretion is intact (Babior 1996). In this case, some enterohepatic recycling of cobalamin should occur in the distal ileum (Howden 2000).

Secondary deficiency

Vitamin B_{12} deficiency is more likely to result from inadequate absorption, defects in vitamin B_{12} metabolism or gastrointestinal disorders than a lack of dietary intake.

Clinical note — Testing for vitamin B_{12} deficiency

Numerous studies have indicated that serum B_{12} levels are an inadequate guide to B_{12} status (Briddon 2003, Carmel 1988, Kapadia 2000, Karnaze & Carmel 1990, Termanini et al 1998). The use of this test has led to poorly defined reference intervals for serum B_{12} (Briddon 2003), potentially delaying the diagnosis and allowing the progression of B_{12} deficiency. Approximately 50% of patients with subclinical disease have normal serum B_{12} levels and older patients present with neurological and psychiatric symptoms without haemotological findings. In addition, use of the oral contraceptive pill may also affect test results (Bor 2004). As a result, this method of testing has lost favour as an adequate measure of B_{12} status. A combination of two tests appears to be more conclusive. Elevated levels of total homocysteine in serum and plasma reflects deficiencies of either folate or B_{12}. MMA is a more specific marker of cobalamin function, but renal insufficiency may affect the results of this test. Therefore, a combination of the two is probably the clearest indicator (Bjorke Monsen & Ueland 2003, FAO/WHO 2002, Kapadia 2000). Preliminary evidence also suggests that overnight fasting urinary MMA concentrations correlate strongly with serum MMA; however, further investigations are required to confirm the application of this test in various populations (Kwok et al 2004). While the use of such markers may improve the assessment of B_{12} deficiency, establishing the cause of deficiency should also be part of the diagnostic approach (Schneede & Ueland 2005).

- Pernicious anaemia: an autoimmune condition affecting gastric parietal cells that produce intrinsic factor; common cause of megaloblastic anaemia, especially in persons of European or African descent (Stabler & Allen 2004).
- Methylmalonic acidaemia: inherited defect in B_{12} metabolism.
- Congenital absence of transcobalamin II.
- Medications that reduce gastric acidity (e.g. H_2 blockers and PPI).
- Atrophic gastritis/gastric atrophy: probably due to a decrease in acid output and intrinsic factor production (Schenk et al 1999). Gastric atrophy is more common in the elderly.
- Intestinal resection of the part of the ileum where absorption takes place or gastric resection, which affects the parietal cells and in turn production of intrinsic factor.
- Achlorhydria (Termanini et al 1998).
- Pancreatic insufficiency: the cobalamin-R-protein complex is split by pancreatic enzymes in the duodenum (Festen et al 1991).
- Ileal dysfunction (Howden 2000): may affect absorption at this site.
- Crohn's disease, irritable bowel disease, coeliac disease: reduced absorption.
- Bacteria and parasites in the intestine may also compete for B_{12}.
- Radiotherapy for rectal cancer: causes a rapid and persistent decrease in B_{12} status as reflected by reduced serum B_{12} combined with increased serum methylmalonic acid (MMA) (Gronlie Guren et al 2004).

The elderly deserve a separate mention as a population at risk of deficiency because of both primary and secondary causes, such as poor dietary intakes, failure to separate vitamin B_{12} from food protein, inadequate absorption, utilisation and storage, as well as drug–food interactions leading to malabsorption and metabolic inactivation (Bradford & Taylor 1999, Dharmarajan et al 2003). Subtle signs of deficiency may include lethargy, weight loss and dementia (Dharmarajan et al 2003).

Elevated levels of serum cobalamin may be a sign of a serious, even life-threatening, disease such as chronic myelogenous leukaemia, promyelocytic leukaemia, polycythaemia vera, hypereosinophilic syndrome, acute hepatitis, cirrhosis, hepatocellular carcinoma and metastatic liver disease. Elevated B_{12} levels, therefore, warrant a full diagnostic work up to assess the presence of disease (Ermens et al 2003).

MAIN ACTIONS

Important cofactor

Vitamin B_{12} is essential for the normal function of all cells. It affects cell growth and replication, the metabolism of carbohydrates, lipids and protein and is involved in fatty acid and nucleic acid synthesis. It is also involved in the production of red blood cells in bone marrow, and activates folacin coenzymes for red blood cell production.

Homocysteine reduction

Methylcobalamin aids in the conversion of homocysteine to methionine by the action of methionine synthase, transferring a methyl group from methylfolate (folic acid).

After conversion from homocysteine, methionine is then converted to *S*-adenosyl-L-methionine (SAMe), important for methylation reactions and protein synthesis. An increase in homocysteine levels and decrease in SAMe levels have been implicated in depression and may also contribute to the neurological symptoms seen in pernicious anaemia (IMG 2003).

Nervous system

Vitamin B_{12} is involved in the synthesis of protein structures in the myelin sheath and nerve cells. As methylation is required for the production of myelin basic protein, a reduction in B_{12} and SAMe will result in demyelination of peripheral nerves and the spinal column (subacute combined degeneration) (FAO/WHO 2002).

Immune system

Vitamin B_{12} acts as an immunomodulator for cellular immunity (Tamura et al 1999).

Liver

Vitamin B_{12} deficiency results in decreased serine dehydratase (SDH) and tyrosine aminotransferase (TAT) activities in rat livers (Ebara et al 2008). In dimethylnitrosamine-induced liver injury in mice, vitamin B_{12} decreased the blood levels of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) suggesting a possible hepatoprotective effect (Isoda et al 2008).

CLINICAL USE

Vitamin B_{12} supplementation is administered using various routes such as intravenous and oral doses. This review will focus on oral supplementation as this is the form generally used by the public and available OTC.

Deficiency: treatment and prevention

Traditionally, vitamin B_{12} supplementation has been used to treat deficiency or prevent deficiency in conditions such as pernicious anaemia and atrophic gastritis, but special consideration should be given to the elderly who are at high risk.

Pernicious anaemia

Pernicious anaemia is caused by a deficiency of intrinsic factor leading to malabsorption of vitamin B_{12}. Signs and symptoms include pallor, glossitis, weakness and neurological symptoms including paraesthesias of the hands and feet, decreased deep-tendon reflexes and loss of sensory perception and motor controls (neurological symptoms may be irreversible). In more progressed conditions confusion, memory loss, moodiness, psychosis and delusional behaviour may be present. Achlorhydria and gastric mucosal atrophy may also occur, further complicating the condition.

Uncomplicated pernicious anaemia is characterised by mild or moderate megaloblastic anaemia without leukopenia, thrombocytopenia or neurologic symptoms. In more advanced cases urgent parenteral administration of vitamin B_{12} and folic acid (typically 100 μg of cyanocobalamin and 1–5 mg of folic acid) is given intramuscularly, as well as blood transfusions.

Atrophic gastritis

Elderly patients with atrophic gastritis appear to have higher rates of vitamin B_{12} deficiency ($P < 0.01$) which responds to B_{12} supplementation (Lewerin et al 2008).

Infants

In infants, severe vitamin B_{12} deficiency can cause neurological symptoms including irritability, failure to thrive, apathy, anorexia and developmental regression which responds well to supplementation (Dror & Allen 2008).

Elderly

Vitamin B_{12} deficiency is common in the elderly, with estimates as high as 43% (Wolters et al 2004). Poor vitamin B_{12} status has been associated with vascular disease, depression, impaired cognitive performance and dementia. Elderly patients (> 60 years) should be monitored for evidence of B_{12} deficiency (a minimum threshold of 220–258 pmol/L (300–350 pg/mL) is desirable in the elderly) and general supplementation with vitamin B_{12} (> 50 μg/day) should be considered (Wolters et al 2004). Significantly higher doses may be required to correct deficiency. A randomised, parallel-group, double-blind, dose-finding trial found that the lowest dose of oral cyanocobalamin required to normalise mild vitamin B_{12} deficiency in the elderly is 647–1032 μg/day, more than 200-fold the recommended dietary allowance (Eussen et al 2005). Conversely another RCT reported that even low doses of B_{12} could improve the vitamin status in elderly people with food-bound vitamin B_{12} malabsorption. The dose required to increase mean serum vitamin B_{12} by 37 pmol/L was 5.9 μg/day (95% CI, 0.9–12.1) (Blacher et al 2007). In another study of elderly people with malabsorption taking 1000 μg/day of crystalline cyanocobalamin for 1 month, 85% of subjects normalised their serum cobalamin concentrations, and all subjects corrected their initial macrocytosis and had medullar regeneration with a mean increase in reticulocyte count (Andres et al 2006). While hearing loss has been associated with poor B_{12} status in the elderly, short term supplementation has so far failed to show benefits (Park et al 2006).

> ***Clinical note — Oral forms are effective***
>
> Vitamin B_{12} is often given parenterally as an intramuscular injection, based on the understanding that oral doses will not be efficacious in cases of malabsorption.
>
> There is now considerable evidence that oral vitamin B_{12} therapy is comparable in efficacy to parenteral therapy, even when intrinsic factor is not present or in other diseases affecting absorption (Andres et al 2005a, b, Bolaman et al 2003, Delpre et al 1999, Kuzminski et al 1998, Lederle 1991, Nyholm 2003, Oh & Brown 2003, Roth & Orija 2004, Vidal-Alaball et al 2005, Wellmer et al 2006). A 2005 Cochrane review suggests 2000 μg/day of oral vitamin B_{12} or 1000 μg initially daily then weekly and monthly may be as effective as intramuscular injections in obtaining short-term haematological and neurological responses in vitamin B_{12}-deficient patients (Vidal-Alaball et al 2005). As rare cases of anaphylaxis may occur with parenteral administration, oral therapy is also considered a safer option with improved cost and compliance (Bilwani et al 2005, Bolaman et al 2003). At doses of 500 μg/day correction of serum B_{12} levels is likely to occur within 1 week to 1 month, with correction of haematological abnormalities after at least 3 months (Andres et al 2005b).

Hyperhomocysteinaemia

Together with folic acid and vitamin B_6, vitamin B_{12} has been shown to reduce high plasma levels of homocysteine, which has been proposed as an independent risk factor for cardiovascular disease

(including atherosclerosis and coronary artery disease), cerebrovascular disease, peripheral vascular disease and venous thromboembolism (Clarke et al 1991, den Heijer et al 1996, Hung et al 2003, Lobo et al 1999, Malinow et al 1989, Selhub et al 1995), exudative ARMD, noise-induced hearing loss, cognitive dysfunction, and adverse pregnancy outcomes (Bjorke Monsen & Ueland 2003, Gok et al 2004, Nowak et al 2005).

Vitamin B_{12} alone may not be sufficient to normalise elevated homocysteine levels (Yajnik et al 2007). As a result, vitamin B_{12} is often recommended in combination with folic acid and vitamin B_6 in conditions for which homocysteine is implicated as a possible causative factor.

Cardiovascular protection

In practice, the relative safety and affordability of combined vitamin B supplementation (B_{12}, folic acid and B_6) make it an attractive recommendation in people with familial hyperhomocysteinaemia. Whether lowering total homocysteine improves cardiovascular mortality and morbidity is questionable as recent large scale clinical trials and meta-analyses have failed to demonstrate any benefits for either B_{12} alone or in combination for reducing overall cardiovascular risk, despite showing a reduction in homocysteine levels (Albert et al 2008, Clarke et al 2007, Mann et al 2008, Marcus et al 2007, Ray et al 2007). Failure of combined B vitamin therapy to reverse inflammatory processes associated with atherogenesis may partly explain the negative results (Bleie et al 2007). The consistent findings of an association between elevated plasma total homocysteine levels and vascular risk is yet to be fully explained, however it is possible that the association is a consequence rather than a cause of disease (Toole et al 2004).

Renal transplant recipients

Although studies investigating the effects of vitamin B_{12} as a stand-alone treatment in this condition are not available, several clinical studies have produced conflicting evidence for the use of combination vitamin B treatment (vitamin B_{12}, folic acid and B_6).

An RCT involving 56 renal transplant patients found that vitamin supplementation with folic acid (5 mg/day), vitamin B_6 (50 mg/day) and vitamin B_{12} (400 μg/day) for 6 months reduced the progression of atherosclerosis. Patients taking the vitamin combination experienced a significant decrease in homocysteine levels and carotid intima–media thickness, which is reflective of early atherosclerosis (Marcucci et al 2003). In a another trial, 36 stable renal transplant recipients with hyperhomocysteinaemia received a similar combination of 5 mg folic acid and 50 mg B_6, in addition to either 1000 μg B_{12} or placebo per day for 6 months. Supplementation decreased blood homocysteine and improved endothelium dependent and independent vasodilatation responses (Xu et al 2008). Despite these preliminary findings, combined therapy using even higher doses (40 mg folic acid, 100 mg B_6 and 2 mg B_{12}) did not improve survival (448 vitamin group deaths vs 436 placebo group deaths) (hazard ratio [HR], 1.04; 95% CI, 0.91–1.18) or reduce the incidence of vascular disease (MI, stroke and amputations) in patients with advanced chronic kidney disease or end-stage renal disease (Jamison et al 2007).

Restenosis after percutaneous coronary intervention

An RCT found that vitamin B_{12} (cyanocobalamin, 400 μg/day), folic acid (1 mg/day) and vitamin B_6 (pyridoxine hydrochloride, 10 mg/day) taken for 6 months significantly decreased the incidence of major adverse events including restenosis after percutaneous coronary intervention (Schnyder et al 2002).

Neural tube defects

Vitamin B_{12} is required to cleave folate, without which folate is not effective and postpartum analysis of serum B_{12} levels has shown an increased risk of NTD in women with low B_{12} status (Groenen et al 2004, Ray & Blom 2003, Suarez et al 2003). Some authors have called for combined fortification of food with folic acid and vitamin B_{12} because there are concerns about masking B_{12} deficiency (Czernichow et al 2005).

Noise-induced hearing loss

Homocysteine levels are significantly higher in subjects with noise-induced hearing loss as compared to healthy controls (Gok et al 2004) and elevated plasma B_{12} levels appear to play a protective role (Quaranta et al 2004).

Recurrent abortion

There appears to be a correlation between low serum B_{12} levels, increased homocysteine levels and early or very early recurrent abortion in some women (Reznikoff-Etievant et al 2002, Zetterberg et al 2002). One small study of five women with a history of very early recurrent abortion found that vitamin B_{12} supplementation resulted in four normal pregnancies (Reznikoff-Etievant et al 2002).

Depression

Elevation of homocysteine and low levels of vitamin B_{12} and folate are commonly seen in depression (Coppen & Bolander-Gouaille 2005). Observational studies have found as many as 30% of patients hospitalised for depression to be deficient in vitamin B_{12} (Hutto 1997). A recent cross-sectional study of 700 community-living, physically disabled women over the age of 65 years found that vitamin B_{12} deficient women were twice as likely to be severely depressed as non-deficient women (Penninx et al 2000). While studies using B_{12} alone could not be located, a prospective, double-blind, placebo-controlled study of 225 hospitalised acutely ill older patients receiving 400 mL of an oral nutritional supplement (106 subjects) or placebo (119 subjects) daily for 6 weeks reported significant increases in plasma vitamin B_{12} concentrations and red-cell folate, and a decrease in depression scores (Gariballa & Forster 2007).

Considering that symptoms of vitamin B_{12} deficiency can manifest as psychological disturbances such as depression, deficiency should be investigated in this population.

AIDS and HIV

Low vitamin B_{12} levels are often observed in patients infected with HIV type 1 (HIV-1) (Remacha & Cadafalch 1999, Remacha et al 1993). One study identified deficiency in 10–35% of all patients seropositive for HIV, presumably as a result of decreased intake, intestinal malabsorption and/or abnormalities in plasma binding proteins or antagonism by the drug azidothymidine. Importantly, as serum cobalamin levels declined, progression to AIDS increased and neurological symptoms worsened.

Cognitive impairment

Women in the highest quartile of plasma vitamin B_{12} levels during mid-life score significantly higher on cognitive function tests in later years and are cognitively equivalent to those 4 years younger (Kang & Grodstein 2005). Supplementation with vitamin B_{12} significantly reverses impaired mental function in individuals with pre-existing low levels (Healton et al 1991, Miller 2003, Refsum & Smith 2003, Tripathi et al 2001, Weir & Scott 1999). A complete recovery was observed in 61% of people with mental impairment due to low levels of vitamin B_{12}, according to one study (Healton et al 1991). It is unclear whether vitamin B_{12} (and folate) deficiency exacerbates a pre-existing but undiagnosed pathological condition or whether it may cause cognitive decline even in normal subjects (Moretti et al 2004).

Prevention when with elevated homocysteine

Hyperhomocysteinaemia has been shown to be an independent risk factor for cognitive dysfunction, as both indirect and direct vascular damage can be caused by homocysteine. It has also been implicated in vascular dementia, with an increased risk of multiple brain infarcts and dementia as homocysteine levels rise. As a result, the homocysteine-lowering action of vitamin B_{12} provides a theoretical basis for its use in these cases. However, a trial using 1000 μg B_{12} alone or in combination with 400 μg folic acid failed to demonstrate a significant improvement in cognitive performance (Eussen et al 2007) and this is consistent with other research in this field (Eussen et al 2006, McMahon et al 2006). Similarly, a systematic review of B_{12}, B_6 and folic acid (alone or in combination) found insufficient evidence to suggest benefits on cognitive function testing in people with either normal or impaired cognitive function (Balk et al 2007).

One study of 370 non-demented 75-year-olds found a twofold increased risk of developing Alzheimer's dementia in subjects with low serum levels of vitamin B_{12} and folate over a 3-year period (Wang et al 2001).

In a study involving 30 mild to moderate dementia patients with vitamin B_{12} deficiency, B_{12} therapy reduced Delirium Rating Scale scores associated with dementia but did not result in significant changes in cognitive function or behavioural symptoms. The B_{12} therapy involved 3 intramuscular injections of methylcobalamin (1 mg) in the first week, oral supplementation with methylcobalamin (1 tablet 3 times a day) for 16 weeks, and 1 intramuscular injection of cyanocobalamin (1 mg) once a month for 6 months (Kwok et al 2008).

Diabetic neuropathy

According to a recent review of seven RCTs, vitamin B_{12} supplementation may improve pain and paraesthaesia in patients with diabetic neuropathy (Sun et al 2005). The studies cited, however, were generally of low quality and more research is required to confirm these results and determine whether positive effects are due to the correction of deficiency or to alteration of abnormal metabolism.

Sleep disorders

A preliminary study investigated the effects of randomly assigned methyl- and cyanocobalamin on circadian rhythms, wellbeing, alertness and concentration after 14 days in 20 healthy subjects (Mayer et al 1996). Methylcobalamin supplementation led to a significant decrease in daytime melatonin levels, improved sleep quality, shorter sleep cycles, increased feelings of alertness, better concentration, and a feeling of waking up refreshed in the morning. It appeared that methylcobalamin was significantly more effective than cobalamin.

Tinnitus

A group of 113 army personnel (mean age 39 years) exposed to military noise was studied, of which 57 had chronic tinnitus and noise-induced hearing loss (Shemesh et al 1993). Of this subset, 47% also had vitamin B_{12} deficiency. Treatment with vitamin B_{12} supplementation produced some improvement in tinnitus and associated symptoms.

OTHER USES

Human trials have shown vitamin B_{12} levels to be low in people with recurrent aphthous stomatitis, suggesting a possible aetiological factor (Piskin et al 2002). An inhalation of vitamin B_{12} mixed solution has been shown to be effective for the treatment of acute radiation-induced mucosal injury (Chen & Shi 2006).

Erythema nodosum

A case report exists of a 38-year-old female diagnosed with erythema nodosum and B_{12} deficiency whose symptoms resolved completely without re-occurrence following vitamin B_{12} therapy (Volkov et al 2005). Testing for deficiency may be advised in such cases.

Atopic dermatitis

A novel use for B_{12} in a topical cream for atopic dermatitis has recently been tested. A prospective, randomised, placebo-controlled phase III multicentre trial involving 49 patients was conducted. Subjects applied the B_{12} cream twice daily to one side of the body and a placebo cream to the contralateral side, according to the randomisation scheme, for

8 weeks. The B_{12} cream was reported to significantly improve the extent and severity of atopic dermatitis and was considered safe and very well tolerated (Stucker et al 2004).

Multiple sclerosis

Multiple sclerosis (MS) and vitamin B_{12} deficiency share common inflammatory and neurodegenerative characteristics and low or decreased levels of vitamin B_{12} have been demonstrated in MS patients and may correlate with early onset (<18 years) (Miller et al 2005). Considering vitamin B_{12} is a cofactor, and myelin formation has important immunomodulatory and neurotrophic effects (Loder et al 2002, Miller et al 2005, Sandyk & Awerbuch 1993), a theoretical basis exists for its use in MS.

Amyotrophic lateral sclerosis (ALS)

Early evidence suggests a possible benefit for long-term ultra-high-dose methylcobalamin (administered IV or IM) for sporadic or familial cases of ALS (Izumi & Kaji 2007), however large-scale clinical trials are required to assess the efficacy and safety of this treatment.

DOSAGE RANGE

Australian RDI

- Adult >13 years: 2.4 μg/day.
- Pregnancy: 2.6 μg/day.
- Lactation: 2.8 μg/day.

Requirements may be higher for elderly people with impaired digestion or absorption.

- Sublingual cyanocobalamin: 1000–2000 μg/day taken 30 minutes before breakfast.
- Pernicious anaemia: generally, vitamin B_{12} 1000 μg IM 2–4 times weekly is given until haematological abnormalities are corrected, and then it is given once monthly. Alternatively, oral B_{12} can be given in very large doses (0.5–2 mg/day). Correction of haematological abnormalities usually occurs within 6 weeks of treatment, but neural improvement may take up to 18 months.
- Homocysteine lowering: 0.5 mg/day (Dusitanond et al 2005).

Note: Sublingual cobalamin is the preferred oral form for many practitioners with methylcobalamin also becoming available in some regions.

ADVERSE REACTIONS

Although adverse effects to parenteral cobalamin have been reported, oral supplements appear to be well tolerated (Hillman 1996, Branco-Ferreira et al 1997).

SIGNIFICANT INTERACTIONS

Carbamazepine

In studies with children, long-term carbamazepine use led to a decrease in vitamin B_{12} levels (Karabiber et al 2003) — observe for signs and symptoms of B_{12} deficiency. Increased intake may be required with long-term therapy.

Gastric acid inhibitors: PPI and H2 receptor antagonists

Gastric acid is required to liberate protein-bound cobalamin. Therefore, vitamin B_{12} concentration may be decreased when gastric acid is markedly suppressed for prolonged periods (Laine et al 2000, Schenk et al 1999, Termanini et al 1998). Studies have shown that omeprazole therapy acutely decreases cyanocobalamin absorption in a dose-dependent manner (Marcuard et al 1994, Saltzman et al 1994) and deficiency may occur with long-term use (Valuck & Ruscin 2004). It should be noted that vitamin B_{12} supplements do not suffer the same fate, as they are not bound to protein — observe for signs and symptoms of B_{12} deficiency; vitamin B_{12} supplements may be required with long-term therapy.

Hydrochlorothiazide

There are a number of medications that have the ability to increase homocysteine levels, such as hydrochlorothiazide (Westphal et al 2003), therefore concurrent use of vitamin B_{12} (with folic acid) may be a useful adjunct — potential beneficial interaction.

Lithium

Lithium administration may result in a decrease in serum B_{12} concentration; however, the clinical significance of these findings is not yet clear (Cervantes 1999). Beneficial interaction is possible.

Metformin

In patients with type 2 diabetes, metformin has been shown to reduce levels of vitamin B_{12} (and folate) and increase homocysteine (Sahin et al 2007). This effect was not demonstrated in women with polycystic ovary syndrome taking metformin and receiving vitamin B_{12} and folate substitution, a daily oral multivitamin tablet, and dietary and lifestyle advice (Carlsen et al 2007). Supplementation may be beneficial.

Oral contraceptive pill

Users of the OCP showed significantly lower concentrations of cobalamin than controls in a 2003 clinical study (Sutterlin et al 2003). However, it would appear that this may be due to an effect on B_{12} binding proteins in serum affecting test results, because total homocysteine and methylmalonic acid markers were unchanged and no symptoms of deficiency were present (Bor 2004) — observe for signs and symptoms of B_{12} deficiency and conduct testing if deficiency is suspected.

Phenobarbital and phenytoin

One clinical study reports that combined long-term use of phenobarbital and phenytoin resulted in significantly increased serum levels of vitamin B_{12} (Dastur & Dave 1987) — observe patients taking this combination.

Prednisolone

Decreased vitamin B_{12} levels have been reported in the cerebrospinal fluid and serum of multiple sclerosis patients following high-dose (1000 mg daily for

PRACTICE POINTS/PATIENT COUNSELLING

- Vitamin B_{12} (cobalamin) is a water-soluble vitamin obtained mostly from animal protein products in the diet.
- There is considerable evidence that oral vitamin B_{12} therapy is comparable in efficacy to parenteral therapy, even when intrinsic factor is not present or in other diseases affecting absorption.
- As numerous studies have indicated that serum B_{12} levels are an inadequate guide to B_{12} status, a combination of total homocysteine and methylmalonic acid is probably the clearest indicator.
- Vitamin B_{12} deficiencies manifest primarily as haematological and neurological disturbances and is estimated to affect 10–15% of individuals over the age of 60 years.
- Traditionally, supplementation is recommended to treat deficiency states or prevent them in people at risk such as in pernicious anaemia or atrophic gastritis.
- When administered together with folic acid and vitamin B_6 (pyridoxine), it is used to reduce homocysteine levels. In this way, vitamin B_{12} is sometimes recommended in conditions where homocysteine is implicated as a possible causative factor.
- Some evidence has shown supplementation can be useful in HIV and AIDS, depression, tinnitus and cognitive impairment when low vitamin B_{12} levels are also present. Preliminary evidence also suggests a possible role for supplementation in diabetic retinopathy and sleep disturbances.
- There are several commonly prescribed pharmaceutical medicines that can reduce vitamin B_{12} absorption when used long term.

10 days) intravenous methylprednisolone (Frequin et al 1993). Given the suggested importance of B_{12} in MS sufferers, a beneficial interaction is possible.

Tetracycline antibiotics

B complexes containing B_{12} may significantly reduce the bioavailability of tetracycline hydrochloride (Omray 1981) — separate doses by at least 2 hours.

CONTRAINDICATIONS AND PRECAUTIONS

- Parenteral cyanocobalamin given for vitamin B_{12} deficiency caused by malabsorption should be given intramuscularly or by the deep subcutaneous route but never intravenously.
- Folic acid supplementation may mask a B_{12} deficiency.
- Treatment with cyanocobalamin should be avoided in cases of altered cobalamin metabolism or deficiency associated with chronic cyanide intoxication (Freeman et al 1999).

PREGNANCY USE

Vitamin B_{12} is considered safe in pregnancy.

Low-dose vitamin B_{12} (1–18 μg/day) does not appear to impact on the circulating level of serum cobalamins or its binding proteins in lactating women (Morkbak et al 2007). If required, higher doses may need to be utilised.

PATIENTS' FAQs

What will this vitamin do for me?

Vitamin B_{12} is essential for healthy growth, development and health maintenance. It will reverse signs and symptoms of deficiency and can alleviate symptoms of tinnitus, poor memory, depression and HIV and AIDS when low vitamin B_{12} levels are also present. There is also some research suggesting some positive effects in diabetic retinopathy and sleep disturbances.

When will it start to work?

In cases of pernicious anaemia, the classical deficiency state, correction of blood abnormalities occurs within 6 weeks; however, correction of nervous system changes is slower and may take up to 18 months.

Are there any safety issues?

Vitamin B_{12} is considered a very safe nutrient.

Vitamin C

HISTORICAL NOTE Vitamin C deficiency has been known for many centuries as scurvy, a potentially fatal condition, dreaded by seamen in the 15th century, who were often forced to subsist for months on diets of dried beef and biscuits. It was also described by the European crusaders during their numerous sieges. In the mid-1700s Lind was the first doctor to conduct systematic clinical trials of potential cures for scurvy, identifying oranges and lemons as successful treatments (Bartholomew 2002). However, it was not until 1928 that vitamin C (then known as antiscorbutic factor) was isolated, leading to mass production in the mid-1930s.

BACKGROUND AND RELEVANT PHARMACOKINETICS

Vitamin C is an essential nutrient for humans and required in the diet on a regular basis, as we are one of few species of animals that cannot synthesise it. This is because humans lack the enzyme L-gulonolactone oxidase, which is required for the conversion of glucose into vitamin C (Braunwald et al 2003).

The bioavailability of ascorbic acid is dependent on both intestinal absorption and renal excretion. Vitamin C, consumed either in the diet or as dietary supplements, is absorbed by the epithelial cells of the small intestine by the sodium vitamin C co-transporter 1 (SVCT1) and subsequently diffuses into the surrounding capillaries and then passes into the circulatory system (Li & Schellhorn 2007). Ultimately, the degree of absorption depends on the dose ingested and decreases as the dose increases. This is because at low concentrations, most vitamin C is absorbed in the small intestine and reabsorbed from the renal tubule, but at high concentrations SVCT1 becomes saturated, which, combined with ascorbate-mediated SVCT1 down-regulation, limits the amount of ascorbic acid absorbed from the intestine and reabsorbed from the kidney (Li & Schellhorn 2007). For this reason, oral vitamin C is best absorbed when it is ingested in small doses at regular intervals. Complete plasmatic saturation occurs at 1000 mg daily with a concentration of around 100 μM (Verrax et al 2008). Pectin and zinc are also able to impair oral absorption. These limitations are bypassed with the use of intravenously administered vitamin C, which can achieve much higher plasma levels than oral administration.

Following its absorption, ascorbic acid is ubiquitously distributed in the cells of the body. Within the body, the highest levels of ascorbic acid are found in the adrenal glands, the white blood cells, skeletal muscles and the brain, especially in the pituitary gland (Verrax et al 2008). Interestingly, the brain is the most difficult organ to deplete of ascorbate. As a polar compound with a relatively large molecular weight, vitamin C cannot readily cross the cell membrane by simple diffusion. The flux of vitamin C in and out of the cell is controlled by specific mechanisms, including facilitated diffusion and active transport, which are mediated by distinct classes of membrane proteins such as facilitative glucose transporters (GLUT) and sodium vitamin C co-transporters (SVCT) respectively (Li & Schellhorn 2007). Once in cells, dehydroascorbic acid (the oxidised form of ascorbate) is rapidly reduced to ascorbate (Harrison & May 2009). Eventually it is metabolised in the liver, filtered by the kidneys, and excreted in the urine. The biological half-life of vitamin C is 8–40 days (NHMRC 2006).

Clinical note — Differences between major forms of vitamin C supplement

Here is a brief summary of the most common forms found in OTC supplements.

- *Ascorbic acid*. The major dietary form of vitamin C.
- *Mineral ascorbates* (also known as non-acid vitamin C). These are buffered forms of vitamin C and believed to be less irritating to the stomach than ascorbic acid. Sodium ascorbate and calcium ascorbate are the most common forms. When mineral salts are taken, both the ascorbic acid and the mineral are absorbed. For example, sodium ascorbate generally provides 131 mg of sodium per 1000 mg of ascorbic acid, and calcium ascorbate provides 114 mg of calcium per 1000 mg of ascorbic acid.
- *Vitamin C with bioflavonoids*. Many bioflavonoids are antioxidant substances and are added to some vitamin C preparations in the belief that this increases the bioavailability or efficacy of vitamin C. Typically, the bioflavonoids are sourced from citrus fruits.
- *Ascorbyl palmitate*. A fat-soluble form of vitamin C formed by esterification with palmitic acid and most often used in topical creams.

CHEMICAL COMPONENTS

Vitamin C exists as both its reduced form (L-ascorbic acid) and its oxidised form (L-dehydroascorbic acid). The two forms interchange in the body in a reversible equilibrium.

FOOD SOURCES

Vitamin C is found in many different fruits and vegetables. The most concentrated food sources are blackcurrants, sweet green and red peppers, hot red peppers, green chilli peppers, oranges and its fresh juice, and strawberries. Other good sources are watermelon, papaya, citrus fruits, cantaloupe, mango, cabbage, cauliflower, broccoli and tomato juice. In practice, vegetables may be a more important source of vitamin C than fruits because they are often available for longer periods during the year.

The vitamin C content of food is strongly influenced by many factors, such as season, transportation, shelf life, storage conditions and storage time, cooking techniques and chlorination of water (FAO/WHO 2002). Cutting or bruising food will reduce its vitamin C content; however, blanching or storing at low pH will preserve it.

Up to 100% of the vitamin C content of food can be destroyed during cooking and storing because the vitamin is sensitive to light, heat, oxygen and alkali (Wahlqvist 2002). Additionally, using too much water during cooking can leach the vitamin from food and further reduce its vitamin C content.

DEFICIENCY SIGNS AND SYMPTOMS

In adults, scurvy remains latent for 3–6 months after reducing dietary intake to less than 10 mg/day (Beers & Berkow 2003). It manifests when the body pools fall below 300–400 mg (NHMRC 2006). Many of the features of frank vitamin C deficiency (scurvy) result from a defect in collagen synthesis.

Early symptoms are:

- weakness
- fatigue and listlessness
- muscular weakness
- petechial haemorrhages and ecchymoses (bruising)
- swollen gums
- poor wound healing and the breakdown of recently healed wounds
- poor appetite and weight loss
- emotional changes such as irritability and depression
- vague myalgias and arthralgias
- congested hair follicles.

Symptoms of more severe deficiency are:

- fever
- drying of the skin and mucous membranes
- susceptibility to infection
- bleeding gums and loosening of teeth
- oedema of the lower extremities
- anaemia
- joint swelling and tenderness, due to bleeding around or into the joint
- oliguria
- pain in the extremities
- haemorrhage
- convulsions
- shock
- eventually death if left untreated.

Clinical note — Deficiencies in smokers

It is well established that smokers have lowered vitamin C status than non-smokers and therefore have higher requirements for vitamin C. Vitamin C status is inversely related to cigarette use (Cross & Halliwell 1993). The depletion of plasma ascorbic acid associated with cigarette smoking was first described in the late 1930s. Reports have shown that low ascorbic acid concentrations in the plasma, leukocytes and urine of both male and female cigarette smokers are associated with increased numbers and activity of neutrophils, which suggests increased utilisation and lower intake, or reduced bioavailability of vitamin C in smokers than in non-smokers (Northrop-Clewes & Thurnham 2007).

Although frank deficiency is uncommon in Western countries, marginal deficiency states are not uncommon.

Primary deficiency

This occurs if there is an inadequate dietary intake, which is often caused by a combination of poor cooking and eating habits. It occurs in areas of urban poverty, during famine and war, in young children fed exclusively on cow's milk for a prolonged period, in the institutionalised or isolated elderly, and in chronic alcoholics (Pimentel 2003, Richardson et al 2002). One Australian hospital identified that 73% of all new admissions had hypovitaminosis C and 30% had levels suggestive of scurvy (Richardson et al 2002).

Secondary deficiency

Factors that increase nutritional requirements include cigarette smoking, pregnancy, lactation, thyrotoxicosis, acute and chronic inflammatory diseases, major surgery and burns, infection and diabetes (Beers & Berkow 2003, FAO/WHO 2002, Hendler & Rorvik 2001, Wahlqvist 2002). Decreased vitamin C absorption in achlorhydria and increased excretion in chronic diarrhoea also increase the risk of deficiency, particularly when combined with poor dietary intake.

MAIN ACTIONS

Vitamin C is an electron donor (reducing agent or antioxidant), and this accounts for most of its biochemical and molecular functions. It is involved in many biochemical processes in the body such as:

- energy release from fatty acids
- metabolism of cholesterol
- reduction of nitrosamine formation in the stomach
- formation of thyroid hormone
- carnitine biosynthesis
- modulation of iron and copper absorption
- corticosteroid biosynthesis
- protection of folic acid reductase, which converts folic acid to folinic acid
- collagen biosynthesis
- tyrosine biosynthesis and catabolism
- neurotransmitter biosynthesis.

The main actions of vitamin C are summarised below.

Antioxidant and pro-oxidant

At physiological concentrations, vitamin C is one of the most important water-soluble antioxidant substances in the body, acting as a potent free-radical scavenger in the plasma, protecting cells against oxidative damage caused by reactive oxygen species (ROS). It scavenges free-radical oxygen and nitrogen species such as superoxide, hydroxyl, peroxyl and nitroxide radicals and non-radical reactive species such as singlet oxygen, peroxynitrite and hypochlorite (FAO/WHO 2002, Hendler & Rorvik 2001). Besides having a direct antioxidant function, it also indirectly increases free-radical scavenging by regenerating vitamin E (Vatassery 1987) and maintaining glutathione in reduced form. Much of the vitamin's physiological role stems from its very strong reducing power (high redox potential) and its ability to be regenerated using intracellular reductants such as glutathione, nicotinamide adenine dinucleotide and nicotinamide adenine dinucleotide phosphate (Chaudière & Ferrari-Iliou 1999).

Paradoxically, ascorbic acid may also function as a pro-oxidant, promoting oxidative damage to DNA in the presence of free transition metals such as copper and iron, which are reduced by ascorbate and, in turn, react with hydrogen peroxide, leading to the formation of highly reactive and damaging hydroxyl radicals. The effect does not appear to be significant under normal physiological conditions in vivo; however, when used at higher pharmacological concentrations (0.3–20 mmol/L), ascorbic acid displays transition metal-independent pro-oxidant activity, which is more profound in cancer cells than healthy cells and causes cell death (Li & Schellhorn 2007).

Whether vitamin C functions as an antioxidant or pro-oxidant is determined by at least three factors: (1) the redox potential of the cellular environment, (2) the presence/absence of transition metals and (3) the local concentrations of ascorbate (Li & Schellhorn 2007).

Maintenance of connective tissue

Vitamin C maintains the body's connective tissue and is essential for the formation of collagen, the major fibrous element of blood vessels, skin, tendon, cartilage and teeth (Morton et al 2001). If collagen is produced in the absence of vitamin C, it is unstable and cannot form the triple helix required for normal tissue structure. Vitamin C is involved in the biosynthesis of other substances important for connective tissue, such as elastin, proteoglycans, bone matrix, fibronectin and elastin-associated fibrillin (Hall & Greendale 1998).

These effects have been harnessed by the dermatological and cosmetic industries and are the rationale for producing topically applied products containing vitamin C.

Brain and nerve function

Ascorbate is involved in neurotransmitter synthesis. It is a cofactor required for the biosynthesis of noradrenaline from dopamine and hydroxylation of tryptophan to produce serotonin. It also acts as a modulator of glutaminergic, cholinergic and GABAergic transmission (Bornstein et al 2003, FAO/WHO 2002, Harrison & May 2009). Furthermore, it is involved in neural maturation and acts as a neuroprotective agent (Harrison & May 2009),

Immunostimulant

Both in vivo and in vitro studies provide evidence of immunostimulant effects, generally at doses beyond RDI levels. Vitamin C favourably modulates lymphocytes and phagocytes, regulates NK cells and can influence antibody and cytokine synthesis under certain situations (Hendler & Rorvik 2001). In high doses, it is a potent immunomodulator and is preferentially cytotoxic to neoplastic cells. Vitamin C enhances the activity of NK cells in vivo and also both B- and T-cell activity (Drisko et al 2003).

Antihistamine

An inverse association has been identified between blood histamine levels and vitamin C status in humans (Johnston et al 1996). In that study, increasing vitamin C status with supplements (up to 250 mg/day) over 3 weeks was shown to decrease histamine levels. It is unclear whether single, high-dose supplementation also affects histamine levels, as two studies using 2 g doses have produced conflicting results (Bucca et al 1990, Johnston et al 1992).

Anticancer

In millimolar concentrations, vitamin C is selectively cytotoxic to many cancer cell lines and has in vivo anticancer activity when administered alone or together with other agents (Hoffer et al 2008). Importantly, pharmacological concentrations of ascorbic acid (0.3–20 mmol/L) are required to find evidence of cytotoxicity in vitro and in vivo, whereas physiological concentrations of ascorbic acid (0.1 mmol/L) do not have any effect on either tumour or normal cells (Li & Schellhorn 2007). The most reliable method of achieving these high doses is with IV administration of vitamin C and not via the oral route, which has limited absorption (Padayatty et al 2006). The effect is clearly dose-dependent and mediated via several mechanisms, such as immunomodulation, inhibition of cell division and growth, gene regulation and induction of apoptosis. One mechanism of cytotoxicity demonstrated in several models is the ability of ascorbate at pharmacological concentrations to exert pro-oxidant activity, generating hydrogen-peroxide-dependent cytotoxicity towards a variety of cancer cells in vitro and in vivo without adversely affecting normal cells (Chen et al 2008, Tamayo & Richardson 2003).

Much investigation has been undertaken to understand how preferential cytotoxicity is achieved; however, the mechanisms are still largely unknown. For example, studies with radioactive-labelled vitamin C have found that tumour cells accumulate more vitamin C than healthy cells, whereas other studies have reported no differences in intracellular concentrations (Prasad et al 2002). There is also some preliminary evidence of

synergistic cytotoxic effects and decreased drug toxicity with some pharmaceutical anticancer agents (Giri et al 1998).

One theory proposed to explain the preferential targeting of tumour cells relates to their overexpression of facilitative glucose transporters (GLUTs) (Gatenby & Gillies 2004) and dehydroascorbic acid, transported by GLUTs, accumulating within the tumour cells, which enables intracellular hydrogen peroxide levels to increase (Verrax et al 2008, Chen et al 2005, Zhang et al 2001). Other intrinsic properties of cancer cells may also be involved, such as reduced concentrations of antioxidant enzymes (e.g. catalase and superoxide dismutase) and increased intracellular transitional metal availability, both of which further augment free-radical production (Li & Schellhorn 2007). Alternatively, it has been suggested that extracellular ascorbate is the source of this anti-cancer effect and is more important than intracellular vitamin C.

Ascorbyl stearate is a lipophilic, vitamin C derivative that has also demonstrated antitumorigenic properties in vitro (Fang et al 2006).

Modulation of gene expression

Many transcription factors, such as NF-jB, AP-1 or PPARs, are redox regulated, and moderate amounts of oxidative stress are known both to modulate gene expression and to signal transduction cascades by affecting kinases, phosphatases as well as Ca^{2+} signalling. L-ascorbic acid may modulate relatively unspecific gene expression by affecting the redox state of transcription factors and of enzymes involved in signal transduction (see Table 1).

OTHER ACTIONS

High oral doses (4–12 g/day in divided doses) can acidify urine.

CLINICAL USE

Vitamin C is an important biological antioxidant and has been a popular nutritional supplement for decades. It is administered as intramuscular or intravenous injections and used topically and orally. This review will chiefly focus on oral and topical use, as these are the forms of vitamin C most commonly used by the public.

TABLE 1 Known or Putative Genes and Enzymatic Activities Responsive to L-Ascorbic Acid (Adapted from Villacorta et al 2007)

Gene	Cellular process involved	Mechanism	Expression/activity with L-ascorbic acid
h1-Calponin	VSMC phenotypic modulation	?	↑
h-Caldesmon	VSMC phenotypic modulation	?	↑
SM22α	VSMC phenotypic modulation	?	↑
α-SM actin	VSMC phenotypic modulation	?	↑
Collagen I	Matrix production	Transcription, mRNA stability	↑
Collagen III	Matrix production	Transcription, mRNA stability	↑
Elastin	Elasticity of arterial wall, VSMC phenotypic modulation	mRNA stability	↓
MMP2	Matrix degradation	?	↓
TIMP1	Inhibits matrix degradation	?	↑
Calponin 1	VSMC phenotypic modulation	?	↑
Myosin heavy chain-1	VSMC phenotypic modulation	?	↑
GATA4	Cardiac development	?	↑
Nkx2.5	Cardiac development	?	↑
ANF	Regulation of cardiac and vascular tone	?	↑
eNOS	Vascular homeostasis	Increased intracellular Ca^{2+}	↑
Prolyl hydroxylase	Stability and secretion of collagen	Co-factor	↑
ICAM-1	Cell adhesion	?	↓
Enzymes involved in carnitine synthesis	Fatty acid metabolism	Co-factor (epsilon-*N*-trimethyllysine hydroxylase and gamma-butyrobetaine hydroxylase)	↑

As with many nutrients, studies associating dietary vitamin intake and disease risk are difficult to interpret. This is because it is difficult to separate the effects of the individual vitamin from the effects of other components in the diet. Where possible, an effort has been made to include information that will help in the interpretation of this type of data.

Deficiency: prevention and treatment

Traditionally, vitamin C supplements are used both to treat and to prevent deficiency. Treatment may include 250 mg vitamin C daily and encouragement to eat fresh fruits and vegetables on a regular basis (Kumar et al 2002), or 100 mg taken 3–5 times daily until 4000 mg has been reached (Braunwald et al 2003). Some deficiency symptoms start to respond within 24 hours, although most take from several weeks to months to resolve completely.

Iron-deficiency anaemia

Ascorbic acid is considered a potent enhancer of iron absorption. Vitamin C facilitates iron absorption by forming soluble complexes and may be used with an iron supplement and nutritious diet in the treatment of iron-deficiency anaemia. It is also recommended for women with menorrhagia in order to reduce the risk of iron deficiency.

Upper respiratory tract infections (URTIs)

Vitamin C is widely used both to prevent and to treat common URTIs, such as the common cold and influenza, largely based on its effects on the immune system, its ability to reduce histamine levels, and the observations that the gastrointestinal absorption of vitamin C increases in the common cold (suggesting an increased demand for this nutrient) and that vitamin C concentrations in the plasma and leucocytes rapidly decline during infection (Wilson et al 1976, Wintergerst et al 2006). Although extremely popular, its usefulness in these conditions is widely debated.

A 2004 Cochrane Review of 29 placebo-controlled studies involving 11,077 participants found that regular ingestion of vitamin C in doses of 200 mg did not reduce the incidence of the common cold in the normal population; however, a subgroup of six trials that involved a total of 642 marathon runners, skiers and soldiers on subarctic exercises did find significant protective effects (Douglas et al 2004). Data from 9676 respiratory episodes suggested that regular vitamin C supplementation was consistently associated with a small reduction in the duration and severity of common cold symptoms; however, the magnitude of the effect was described as small. When high doses of vitamin C have been started after the onset of cold symptoms, there has been no consistent effect on either the duration or the severity of symptoms. Equivocal results were obtained in one large trial that used a dose of 8 g at the onset of symptoms, whereas two trials using supplementation for 5 days did report a benefit.

Since then, a long-term study reported that use of 500 mg/day vitamin C significantly reduced the risk of the common cold (relative risk 0.34), although no reduction in severity or duration was seen (Sasazuki et al 2006). The double-blind RCT was conducted over 5 years and, due to protocol amendment, these results should be viewed conservatively.

There are a number of factors that may be contributing to the inconsistent results obtained to date, such as the variable characteristics of the subjects studied, type of infecting virus, lack of control for dietary vitamin C intake and differences in measures of outcomes. Clearly, further investigation is required to clarify many issues surrounding the use of vitamin C supplements for URTIs. In practice, naturopaths often recommend megadoses of vitamin C (taken frequently, in small amounts), which are well beyond the doses investigated so far, and often report good results. Although anecdotal, it is interesting to note that little research has investigated this method.

Dermatological uses

Vitamin C is used as an oral supplement or topical application in a number of dermatological conditions.

Wound healing

Vitamin C is important for effective wound healing, as deficiency contributes to fragile granulation tissue and therefore impairs the wound-healing process (Russell 2001).

In vitro studies with skin graft samples have demonstrated that vitamin C extends cellular viability, promotes formation of an epidermal barrier and promotes engraftment (Boyce et al 2002). In this way, vitamin C is used to enhance wound healing before surgery has commenced.

Numerous case reports of surgical and dental patients generally suggest a use for vitamin C supplementation in doses beyond RDI as a means of enhancing the rate of wound healing (Ringsdorf & Cheraskin 1982). One early double-blind study found that vitamin C (500 mg twice daily) resulted in a significant mean reduction in pressure-sore area of 84% after 1 month compared with 43% in the placebo group (Taylor et al 1974). The mean rates of healing were 2.47 cm^2 for vitamin C and 1.45 cm^2 for the placebo.

Photo-damaged skin

Two double-blind studies investigating the effects of topical preparations of vitamin C on photo-damaged skin have demonstrated good results after 3 months' use (Fitzpatrick & Rostan 2002, Humbert et al 2003). One study tested a topical application of 5% vitamin C in a cream base, whereas the other used a newly formulated vitamin C complex having 10% ascorbic acid (water-soluble) and 7% tetrahexyldecyl ascorbate (lipid-soluble) in an anhydrous polysilicone gel base.

Prevention of sunburn

One controlled study found oral vitamin C (2000 mg/day) in combination with vitamin E (1000 IU/day) had a protective effect against sunburn after 8 days' treatment in human subjects (Eberlein-Konig et al 1998).

Similar results have been obtained for topical vitamin C preparations in several animal models (Darr et al 1992, 1996, Lin JY et al 2003) and a small human study (Keller & Fenske 1998). The latter found that application of an aqueous 10% L-ascorbic acid solution after UVB radiation produced a significant reduction in the minimal erythema dose and a less intense erythematous response than controls.

Reduction in all-cause mortality

Several studies have identified an inverse association between plasma ascorbate levels, vitamin C intake and all-cause mortality.

In the Western Electric Company Study, data on diet and other factors were obtained in 1958 and 1959 for a cohort of 1556 employed middle-aged men and an inverse association between vitamin C and mortality was identified (Pandey et al 1995). The next year, a prospective cohort study conducted with 725 older adults also identified an inverse relationship between vitamin C blood concentrations and total mortality during a 12-year follow-up (Sahyoun et al 1996). Similar results were obtained in the large EPIC-Norfolk study of 19,496 men and women aged 45–79 years (Khaw et al 2001). Plasma ascorbate concentration was inversely related to mortality from all causes, and from cardiovascular disease and ischaemic heart disease in both men and women. Risk of mortality in the group with the highest intake was about half that of the low intake group and was independent of age, systolic blood pressure (SBP), serum cholesterol, cigarette smoking, diabetes or supplement use.

The Second National Health and Nutrition Examination Survey (NHANES II) Mortality Study further confirmed the inverse association between plasma ascorbate and risk of dying from all causes; however, this study identified a gender difference (Loria et al 2000). After adjustments for race, educational level, number of cigarettes smoked at baseline, serum total cholesterol, SBP, body mass index, diabetes status and alcohol consumption, men in the lowest serum ascorbate quartile (serum ascorbate concentrations < 28.4 micromol/L) had a 57% higher risk of dying from any cause than did men in the highest quartile (> 73.8 micromol/L). Additionally, men in the lowest serum ascorbate quartile had double the risk of dying from cancer than those in the highest quartile after adjustment for age. The dose corresponds to approximately 60 mg/day vitamin C. In contrast, among women no association was observed between quartiles of serum ascorbate concentration and total mortality or mortality from cardiovascular disease or cancer.

A gender difference was also reported in the NHANES I Epidemiologic Follow-up Study (NHEFS) (Enstrom et al 1992). Vitamin C intakes > 50 mg/day plus regular supplement use were associated with reduced mortality, compared with intakes < 50 mg/day in men, but apparently not in women.

Prevention of cardiovascular disease

The association between vitamin C and cardiovascular disease prevention is still unclear, although several themes are emerging as evidence accumulates. In general, laboratory, epidemiological and observational follow-up studies suggest that vitamin C is associated with reduced incidence of cardiovascular disease, although not all studies are positive (Houston 2005). Studies have looked at blood levels, dietary intake and supplemental vitamin C; in some studies, vitamin C is co-administered with other nutrients (often vitamin E), making it difficult to assess the contribution of vitamin C alone (Carr & Frei 1999, Khaw et al 2001, Knekt et al 2004, Kushi et al 1996, Lopes et al 1998, MRC/BHF 2002, Ness et al 1996, Nyyssonen et al 1997, Osganian et al 2003). Apart from these and other well-recognised confounding phenomena, the inconsistency is due at least in part to our limited understanding of the mechanisms of action of this vitamin on different pathophysiological variables contributing to cardiovascular complications; as such, more focused mechanistic studies on the interaction of ascorbic acid with contributors of specific vascular pathology are required (Li & Schellhorn 2007). Overall, it appears that if a protective effect is observed with supplementation, it is most likely with doses above RDI and long-term use, and in populations with a substantial proportion of people who have low or deficient intakes of vitamin C.

Possible mechanisms

According to a 2001 review, ascorbic acid is inversely related to several risk factors and indicators of atherosclerotic cardiovascular disease, including hypertension and elevated concentrations of LDL, acute phase proteins and haemostatic factors (Price et al 2001). More specifically, vitamin C inhibits oxidative modification of LDL cholesterol directly through free-radical scavenging activity according to in vitro data, and indirectly by increasing glutathione and vitamin E concentrations within cell membranes. This has been demonstrated against the pro-oxidant combination of homocysteine and iron (Alul et al 2003) and may have implications for other diseases such as Alzheimer's dementia.

More recently, evidence suggests that other mechanisms are also likely to be involved. Vitamin C is linked to endothelial function and glucose metabolism. It improves endothelial dysfunction in smokers, renal transplant recipients, patients with cardiovascular disease after a fatty meal, people with intermittent claudication diabetes and those with hypertension (Kaufmann et al 2000, Ling et al 2002, Silvestro et al 2002, Solzbach et al 1997, Williams et al 2001), but not in healthy elderly people (Singh et al 2002). It is also required for collagen synthesis and metabolism, and has been shown to reduce arterial stiffness and platelet aggregation in healthy male volunteers, smokers and non-smokers, and diabetics (Schindler et al 2002, Wilkinson et al 1999). These effects are often observed with doses several times higher than current RDI levels. In vivo studies further indicate that vitamin C decreases carotid wall thickness, down-regulates inducible nitric oxide synthase (iNOS) expression, normalises gene expression of antioxidant enzymes and inhibits plaque maturation (Kaliora et al 2006). Villacorta

et al (2007) assessed the combination of Vitamin C and E and concluded that the combination is able to protect the damaged vascular wall not only by limiting cell proliferation, but also by mediating the process that leads to the stabilisation of a fibrous cap by influencing components of the extracellular matrix.

Clinical studies involving vitamin C supplementation

In the pooled analysis from the Pooling Project of Cohort Studies on Diet and Coronary Disease, those subjects with higher supplemental vitamin C intake (median intake of 756 mg/day) had a 24% reduced risk of coronary heart disease than those in the lowest quintile, whereas dietary vitamin C had no significant protective effect (Knekt et al 2004). The lower risk was independent of non-dietary risk factors and related to dose. The researchers also adjusted for many relevant constituents of foods (e.g. dietary fibre and saturated fat) and found this adjustment had no effect on the association.

The recent Women's Antioxidant Cardiovascular Study (WACS) tested the effects of vitamin C (500 mg daily), vitamin E (600 IU every other day) and beta-carotene (50 mg every other day) on the combined outcome of myocardial infarction (MI), stroke, coronary revascularisation or cerebrovascular disease (CVD) death among 8171 female health professionals at increased risk. Participants were 40 years of age or older, with a prior history of CVD or three or more CVD risk factors, and were followed for an average 9.4 years. The study's factorial design enabled a comparison to be made between individual test agents as well as combination therapy. Overall, there was no significant effect for the individual nutrients vitamin C, vitamin E or beta-carotene on the primary combined endpoint, or on the individual secondary outcomes of MI, stroke, coronary revascularisation or CVD death. A marginally significant reduction in the primary outcome with active vitamin E was observed among the pre-specified subgroup of women with prior CVD (RR = 0.89, $P = 0.04$). With regard to combination therapy, people receiving both vitamins C and E experienced fewer strokes ($P = 0.03$), but there were no other significant findings (Cook et al 2007).

Effects on blood pressure

Although epidemiological evidence and prospective clinical trials point strongly to a role of vitamin C in reducing blood pressure in hypertensive and normotensive subjects, controlled studies have been inconsistent (Houston 2005). Interpretation of these results is difficult, as some studies lack a control group, have no baseline readings, use variable vitamin C doses and population characteristics, and do not report serum vitamin C or oxidative stress status. Overall, it appears that doses between 100 mg and 1000 mg of vitamin C daily are required for a reduction in blood pressure, with greater reduction in systolic blood pressure (SBP) than diastolic blood pressure (DBP) and greater response in people with higher initial value.

A 1997 review of epidemiological studies showed some inverse associations between SBP, DBP or both and vitamin C plasma concentration or intake (Ness et al 1997). Three more recent studies have supported this finding (Bates et al 1998, Block 2002, Block et al 2001). Over the past 10 years, four intervention studies investigated the effects of vitamin C supplementation, with three producing positive results (Duffy et al 1999, Fotherby et al 2000, Galley et al 1997, Ghosh et al 1994). The doses used were typically 250 mg twice daily for a period of 6–8 weeks, although effects have been reported after 4 weeks' treatment.

The negative study by Ghosh et al showed a significant reduction in both SBP and DBP with ascorbic acid. This became non-significant when compared with the placebo responses, although the placebo and ascorbic acid groups were not evenly matched for baseline plasma ascorbate concentration.

Additionally, plasma ascorbate concentrations have been shown to be inversely correlated to pulse rate in one cross-sectional study involving 500 subjects (Bates et al 1998).

Nitrate tolerance

Preliminary studies seem to support the role of vitamin C in attenuating the development of nitrate tolerance. Three human studies have found that vitamin C administration prevents the development of nitrate tolerance (Bassenge et al 1998, Watanabe et al 1998a, 1998b). Although the mechanism responsible is not yet known, results from a double-blind study using an acute dose of 2 g have suggested that vitamin C is likely to protect nitric oxide from inactivation by oxygen free radicals (Wilkinson et al 1999), which could in part explain its observed effects.

Myocardial infarction (MI)

Two prospective studies in men have suggested that ascorbic acid deficiency and marginal deficiency predict subsequent MI, independent of classical risk factors.The first, a 5-year prospective population study of 1605 middle-aged Finnish men, free of coronary disease at baseline, found that a significantly higher percentage (13.2%) of the 91 men with baseline plasma vitamin C concentrations less than 11.4 micromol/L (2.0 mg/L) experienced MI, compared with men with higher plasma vitamin C levels (Nyyssonen et al 1997). These results are particularly impressive because low plasma ascorbate was the strongest risk factor of all the measured factors. The second, a 12-year follow-up study, revealed a significantly increased relative risk of ischaemic heart disease and stroke at initially low plasma levels of vitamin C (< 22.7 micromol/L), independently of vitamin E and of the classical cardiovascular risk factors (Gey et al 1993).

In contrast, one smaller study involving 180 male patients with a first acute MI, but no recent angina, failed to detect an association between low plasma concentration of vitamin C and the risk of acute myocardial infarction (Riemersma et al 2000).

There is a large body of evidence that reactive oxygen species produced during myocardial ischaemia and reperfusion play a crucial role in myocardial damage and endothelial dysfunction. As a result, there has been some investigation to determine whether antioxidant supplementation (chiefly vitamins C and E) may improve the clinical outcome of patients with acute MI and limit the size of the infarct.

According to a large, randomised, double-blind, multicentre trial of 800 patients (mean age 62 years) with acute MI and receiving standard care, co-treatment with vitamin C (1000 mg/12 h infusion) followed by 1200 mg/day orally and vitamin E (600 mg/day) for 30 days resulted in significantly less frequent incidence of re-infarction and other post-MI complications compared to a placebo (14% versus 19% respectively) (Jaxa-Chamiec et al 2005). Another randomised, double-blind, placebo-controlled study of 37 patients with acute MI investigated the effects of starting supplementation with vitamins C and E (600 mg/day each) on the first day of symptoms and continuing for a further 14 days (Bednarz et al 2003). Active treatment resulted in significantly lower exercise-induced QT-interval dispersion (QTd) compared to a placebo, although baseline QTd was similar in both groups. A prospective, randomised study of 61 patients further suggests that oral vitamin C administration (1 g/day) could be beneficial for patients at higher thrombotic risk post-MI, such as those with diabetes (Morel et al 2003).

Cancer: prevention and treatment

One of the most important modifiable determinants of cancer risk is diet. Several research panels and committees have independently concluded that high fruit and vegetable intake decreases the risk of many types of cancer and, because vitamin C is present in large quantities in these foods, it is plausible that the reduction in cancer risk associated with the consumption of fruits and vegetables may be, at least in part, attributable to dietary vitamin C (Li & Schellhorn 2007).

Prevention

Epidemiological evidence of a protective effect of dietary vitamin C for non-hormone-dependent cancers is strong (Block 1991a, 1991b). The majority of studies in which a dietary vitamin C intake was calculated have identified a statistically significant protective effect, with high intake conferring approximately a twofold protective effect compared with low intake. In general, most have shown that higher intakes of vitamin C are associated with decreased incidence of cancers of the mouth, throat and vocal chords, oesophagus and stomach, pancreas, colon, rectum, renal cell and lung (Cohen & Bhagavan 1995, FAO/WHO 2002, Jenab et al 2006, Negri et al 2000, You et al 2000). More recently, a case control study of men in New York found that a higher intake of vitamin C was associated with reduced risk of prostate cancer (McCann et al 2005).

Clinical note — Vitamin C for cancer: a historical perspective

More than three decades ago, the well-known team of Ewan Cameron and Linus Pauling started investigating the effects of high doses of continuous intravenous vitamin C and oral supplements in treating advanced, incurable cancer. The idea of using vitamin C was born out of the recognition that the outcome of every cancer is determined to a significant extent by the individual's inherent resistance, which in turn is influenced by the availability of certain nutritional factors such as ascorbic acid (Cameron 1982). They have published the results of several trials that have shown enhanced quality of life for some terminal patients and also improvements in objective markers. As a result, a protocol for the use of vitamin C in the treatment of cancer has been developed at the Vale of Leven Hospital, the chief site of Cameron and Pauling's investigations (Cameron 1991). The protocol emphasises the importance of using an initial course of intravenous ascorbate, followed by a maintenance oral dose. Although their results are encouraging, they have been criticised because randomised double-blind principles were not adopted.

Two other large studies have identified inverse associations between dietary vitamin C and breast cancer risk (Michels et al 2001, Zhang et al 1999). More specifically, the Nurses' Health Study, which involved 83,234 women, detected a strong inverse association between total vitamin C from foods and breast cancer risk among premenopausal women with a positive family history of breast cancer (Zhang et al 1999). Those who consumed an average of 205 mg/day of vitamin C from foods had a 63% lower risk of breast cancer than those who consumed an average of 70 mg/day. A large Swedish population-based prospective study that comprised 59,036 women found that high dietary intakes of ascorbic acid (mean intake 110 mg/day) reduced the risk of breast cancer among women who were overweight and/or had a high intake of linoleic acid (Michels et al 2001).

More recently, a case–control study nested within the European Prospective Investigation into Cancer and Nutrition (EPIC) identified an inverse risk of gastric cancer in the highest versus lowest quartile of plasma vitamin C (Jenab et al 2006). The inverse association was more pronounced in subjects consuming higher levels of red and processed meats, a factor that may increase endogenous N-nitroso compound production. It has been proposed that vitamin C protects against gastric cancer because it inhibits carcinogenic N-nitroso compound production in the stomach and acts as a free-radical scavenger.

Overall, it appears that the protective effect is dose-dependent, with studies finding significant cancer risk reductions in people consuming at least 80–110 mg of vitamin C daily in the long term (Carr & Frei 1999).

Clinical studies

One of the first published studies by Cameron and Pauling (1974) was a Phase I–II study in 50 patients with advanced, untreatable malignancies, in which both subjective and objective markers were evaluated. They observed that 27 patients failed to respond to treatment; however, three patients experienced stabilisation of disease, tumour regression occurred in five patients and tumour haemorrhage and necrosis occurred in four patients. Two years later, the same research team published a report that compared the survival rates of 100 terminal cancer patients given supplemental ascorbate as part of their routine management with 1000 patients who were not given the supplement, and observed the mean survival time to be more than 4.2 times longer for the ascorbate subjects (> 210 days) than for the controls (50 days) (Cameron & Pauling 1976).

In subsequent years, two randomised, placebo-controlled studies investigating the effects of oral vitamin C supplementation (10 g/day) in terminal cancer patients failed to detect a significant difference in outcome (Creagan et al 1979, Moertel et al 1985). These two studies are often cited as evidence disproving the benefits of vitamin C in cancer treatment; however, the different routes of administration investigated in these studies is an important factor central to the discrepant results (Padayatty & Levine 2000). Maximal plasma vitamin C concentrations achievable by oral administration are limited by the kidney, which eliminates excess ascorbic acid through renal excretion, whereas IV injection bypasses the renal absorptive system, resulting in elevated plasma concentrations to high levels. As such, it has been argued that only IV administration of high-dose ascorbate can produce millimolar plasma concentrations that are toxic to many cancer cell lines.

Scientific interest in the interaction between ascorbic acid and cancer has been reawakened in recent years, with new evidence that in millimolar concentrations (only achievable after parenteral administration) vitamin C is selectively cytotoxic to many neoplastic cell lines, potentiates cytoxic agents and demonstrates anticancer activity alone and in combination with other agents in tumour-bearing rodents (Hoffer et al 2008). Simultaneously, theoretical interest has arisen in the potential of redox-active molecules like menadione, trolox and ascorbic acid to modify cancer biology, especially when administered with cytotoxic drugs.

Intravenous vitamin C

Intravenous administration of vitamin C achieves much higher plasma and urine concentrations than oral dosing and has been proposed as the only viable means of achieving the high concentrations required to induce the antitumour effects exhibited by the vitamin (Padayatty et al 2004). Case studies suggest that this approach can improve patient well-being and, in some cases, reduce tumour size and improve survival (Padayatty et al 2006, Riordan et al 2005).

A safety study conducted in 2005 involved 24 late-stage terminal cancer patients who were administered continuous vitamin C infusions of 150–710 mg/kg/day for up to 8 weeks (Riordan et al 2005). This treatment regimen increased plasma ascorbate concentrations to a mean of 1.1 mmol/L and was considered relatively safe. The most common side effects reported were nausea, oedema and dry mouth or skin, and two 'possible' adverse events occurred. One was a patient with a history of renal calculi who developed a kidney stone after 13 days of treatment, and another was a patient who experienced hypokalaemia after 6 weeks. Interestingly, the majority of patients were vitamin-C-deficient before treatment.

Clinical trials for phases I and II are currently being conducted using intravenously administered vitamin C in patients with solid tumours. The phase I study was primarily conducted to determine a recommended phase 2 dose, with secondary objectives to define any toxic effects, detect any preliminary antitumour effects and monitor for preservation of or improvement in quality of life. In the first phase I trial published in 2008, patients with advanced cancer or haematologic malignancy were assigned to sequential cohorts infused with 0.4, 0.6, 0.9 and 1.5 g ascorbic acid/kg body weight three times weekly, delivered intravenously. This protocol achieved plasma ascorbic acid concentrations of > 10 μM for more than 4 hours, which is considered sufficient to induce cancer cell death according to in vitro research. In addition, all patients were provided with a daily multivitamin tablet (Centrum Select, Wyeth) and 400 IU d-alpha-tocopherol twice daily with meals, and, on non-infusion days, 500 mg ascorbic acid twice daily to obviate large shifts in plasma ascorbic acid concentrations. No unusual biochemical or haematologic abnormalities were observed, and there were no changes in the social, emotional or functional parameters of quality of life in any cohort. Unlike in the previous case series by Cameron and Pauling (1974), in which acute tumour haemorrhage and necrosis were reported, these effects were not seen in this study (Hoffer et al 2008). Researchers concluded that the promise of ascorbic acid in the treatment of advanced cancer may lie in its combination with cytotoxic agents, where high concentrations might modify either toxicity or response. A phase I–II clinical trial is being planned that will combine IV ascorbic acid with chemotherapy as a first-line treatment in advanced stage non-small-cell lung cancer, using the dose determined from this study.

Based on the available evidence of antitumour mechanisms and these case reports, further research into this approach is clearly warranted.

Adjunct to oncology treatments

Whether vitamin C improves or hinders responses to standard oncology treatment has been the focus of intense debate for many decades. There are in vitro studies showing that vitamin C can enhance the antitumour activity of cisplatin and doxorubicin (Abdel-Latif et al 2005, Kurbacher et al 1996, Reddy et al 2001, Sarna & Bhola 1993). In vivo evidence shows vitamin C enhances the effectiveness of 5-fluorouracil, doxorubicin, cyclophosphamide and vincristine (Lamson & Brignall 2000, Nagy et al

Clinical note — The debate continues … to vitamin C or not?

One research group based at the University of Colorado has produced evidence that suggests that vitamin C and other antioxidant nutrients may not only protect healthy cells from damage, but also improve the antitumour effects of standard treatment (Gottlieb 1999). They are currently conducting further research to identify how cell selectivity occurs, but propose that cancer cells may have lost the normal homeostatic regulatory mechanism that stops excessive concentrations of antioxidants from entering the cell. As intracellular levels rise, a series of reactions occurs, resulting in growth inhibition and cell death. Another group at Memorial Sloan Kettering Cancer Centre (Gottlieb 1999) argues that tumours already contain higher levels of ascorbic acid than normal cells and have identified a mechanism to explain this observation. As such, they advocate against the use of vitamin C when cytotoxic agents that rely on free-radical production are being used (see Ch 10 for further discussion).

2003), whereas other studies find no change in drug effect. Although these results are promising, no large randomised studies are available to confirm their significance in humans.

Most recently, vitamin C inactivated the effects of bortezomib, a new proteasome inhibitor approved by the US Food and Drug Administration for the treatment of patients with relapsed multiple myeloma (Zou et al 2006). Interestingly, drug inactivation was not achieved through antioxidative mechanisms.

Evidence from experimental models suggests that vitamin C may also reduce drug toxicity in a dose-dependent manner (Giri et al 1998, Greggi Antunes et al 2000).

Diabetes

Vitamin C has several actions that provide a basis for its use in diabetes. It has been reported to lower erythrocyte sorbitol concentrations (important for preventing complications in type 1 diabetes), improve endothelial function (important for slowing atherosclerosis) and reduce blood pressure (Beckman et al 2001, Cunningham 1998). Plasma vitamin C levels seem to play a role in the modulation of insulin activity in aged healthy or diabetic subjects (Paolisso et al 1994) and are inversely related to glycosylated haemoglobin. Additionally, increased free-radical production has been reported in patients with diabetes mellitus as a result of hyperglycaemia, which directly induces oxidative stress (Ceriello et al 1998).

Blood glucose

At this stage there are few studies that test the effects of supplemental vitamin C on plasma glucose levels directly. Although one early study demonstrated that an oral dose of 1500 mg vitamin C reduces plasma glucose levels in patients with type 2 diabetes (Sandhya & Das 1981), no further published studies confirm this result.

Endothelial function

The results of studies investigating the role of vitamin C on endothelial function in diabetes have attracted recent interest.

A double-blind, placebo-controlled study demonstrated that chronic oral vitamin C supplementation (500 mg/day) in type 2 diabetes significantly lowered arterial blood pressure and improved arterial stiffness compared with a placebo (Mullan et al 2002). After 1 month's treatment, SBP fell from 142.1 to 132.3 mmHg, mean pressure from 104.7 to 97.8 mmHg, DBP from 83.9 to 79.5 mmHg and peripheral pulse pressure from 58.2 to 52.7 mmHg, whereas placebo had no effect.

A randomised study of women with a history of gestational diabetes showed that ascorbic acid supplementation resulted in a significant improvement of endothelium-dependent flow-mediated dilatation, with no effect seen for a placebo (Lekakis et al 2000).

However, a randomised, double-blind, placebo-controlled study of vitamin C (800 mg/day for 4 weeks) concluded that high-dose oral vitamin C therapy resulted in incomplete replenishment of vitamin C levels and does not improve endothelial dysfunction and insulin resistance in type 2 diabetes (Chen et al 2006).

The mechanism of action appears to involve several steps, such as reduction in LDL oxidation, enhanced endothelial NO synthase activity and NO bioavailability and reduced insulin resistance, which can cause endothelium-dependent, NO-mediated vasodilation.

Eye health

Diabetes mellitus is associated with a number of ocular complications that can eventually lead to blindness. Vitamin C is found in high concentration in the eye and is thought to be important for protection against free radicals. This may have special significance for people with diabetes mellitus, as most studies have found that their circulating vitamin C levels are at least 30% lower than in people without the disease (Peponis et al 2002). One study demonstrated that a combination of oral vitamins C (1000 mg/day) and E (400 IU/day) improved tear film stability, tear secretion and the health of the ocular surface in diabetic patients.

Because of its safety, cost effectiveness and generally encouraging results, a strategy of adding 200–600 mg of vitamin C to a healthy diet is worth considering for individuals with diabetes type 1 or 2.

Prevention of cataracts

Ascorbate has long been known to accumulate in tears and other biofluids, such as cerebrospinal fluid relative to plasma (Patterson & O'Rourke 1987), and lowered levels of vitamin C in the eye have been associated with increased oxidative stress in the human cornea (Shoham et al 2008). Ascorbic acid is thought to be a primary substrate in ocular protection because of its high concentration in

the eye. Within the cell, vitamin C helps to protect membrane lipids from peroxidation by recycling vitamin E (May 1999). It is present at high concentrations in vitreous humor (Hanashima & Namiki 1999), cornea (Brubaker et al 2000) and tear film (Dreyer & Rose 1993).

Numerous observational and prospective clinical studies have been performed to examine the effect on cataracts of vitamin C alone or in combination with other antioxidants. Several epidemiological studies have identified an association between vitamin C and cataract incidence (Ferrigno et al 2005, Jacques & Chylack Jr 1991, Jacques et al 1988, Valero et al 2002); however, studies investigating whether supplementation is protective have produced mixed results (Chasan-Taber et al 1999, Chylack Jr et al 2002, Hammond & Johnson 2002, Jacques et al 1997, 2001, Kuzniarz et al 2001, Seddon et al 1994, Taylor et al 2002).

Results from the Harvard Nurses' Health Study, Physicians' Health Study, the Beaver Dam Eye Study and the Australian Blue Mountains study suggest that if protective effects are to be seen, they are most likely when vitamin C is taken for a long period (5–10 years or more) and/or used as part of a multivitamin combination (Kuzniarz et al 2001, Mares-Perlman et al 2000, Seddon et al 1994, Taylor et al 2002).

It is suspected that vitamin C protects the lens of the eye from oxygen-related damage over time by both direct free-radical scavenging activity and indirect activity. This is achieved primarily by protecting endogenous alpha-tocopherol (the major lipid-soluble antioxidant of retinal membranes) against oxidation induced by UV radiation and by regenerating it (Stoyanovsky et al 1995).

Atopy and asthma

Vitamin C is the major antioxidant present in the extracellular fluid lining of the lung, where it protects against both endogenous free radicals (produced as a by-product of inflammation) and environmental free radicals (such as ozone in air pollution). According to many epidemiological studies, dietary intake of vitamin-C-rich foods or serum ascorbate is associated with improved lung function in both asthmatic and normal subjects (Devereux & Seaton 2005, McDermoth 2000, Kelly 2005). Oxygen metabolites can play a direct or indirect role in the modulation of airway inflammation. Many studies suggest that superoxide dismutase and free-radical scavengers in the blood are significantly lower in asthma, and document a correlation between asthmatic severity and ROS products in asthmatic subjects (Shanmugasundaram 2001, Vural 2000). Not surprisingly, low blood concentrations of vitamin C have been found in mild asthmatic subjects (Rahman 2006).

Despite a theoretical basis for its use in lung diseases such as asthma, its value in this disease is controversial. A 2001 Cochrane Review of three studies concluded that current evidence is insufficient to recommend a specific role for vitamin C in the treatment of asthma and that a large-scale RCT is required to clarify its role (Kaur et al 2001).

Clinical note — Do asthmatic lungs need more antioxidant protection?

In 1999, Kelly et al found that people with mild asthma have low levels of antioxidant nutrient vitamins E and C in their lung lining fluid, even though blood levels of these vitamins may be normal or increased. This observation, together with other factors, indicated that the asthmatic lung is exposed to greater oxidative stress in people with asthma than in non-asthmatics. The researchers suggested that the inflammatory cells in the lungs of asthmatic patients generate more free-radical species than those in healthy people, adding to bronchoconstriction, increased mucus secretion and increased airways responsiveness. Given that oral supplementation in asthma has produced inconsistent results, chief researcher Frank Kelly suggests that future studies should focus on other administration forms such as vitamin C inhalers (personal communication, Melbourne, 1998).

An updated Cochrane Review published in 2004 included new data from a study of 201 adults taking inhaled corticosteroids and came to a similar conclusion, stating that evidence is currently conflicting (Ram et al 2004).

Alternatively, the evidence for its use in exercise-induced asthma appears stronger, as three human studies have produced positive results when vitamin C was used as pretreatment in doses ranging from 500 mg to 2000 mg (Cohen et al 1997, Miric & Haxhiu 1991, Schachter & Schlesinger 1982).

Bone mineral density

Although the relationship between calcium, vitamin D and bone mineral density (BMD) is well known, other nutrients, such as vitamin C, are also critical for bone development, repair and maintenance (Ilich et al 2003).

Data collected from 13,080 adults enrolled in the Third National Health and Nutrition Examination Survey (NHANES III) from 1988 to 1994 have identified an association between dietary and serum ascorbic acid, BMD and bone fracture (Simon & Hudes 2001). Dietary ascorbic acid intake was independently associated with BMD among premenopausal women and postmenopausal women without a history of smoking or oestrogen use. Additionally, fracture risk fell by 49% in postmenopausal women (with a history of smoking and oestrogen use) who had high serum vitamin C levels.

Vitamin C supplementation

Two controlled studies have investigated the effects of long-term vitamin C supplementation in postmenopausal women and found that it increases BMD (Hall & Greendale 1998, Morton et al 2001). Both studies identified a positive association with BMD in postmenopausal women with dietary calcium intakes of at least 500 mg or those taking calcium supplements. The effect was especially marked in those women taking calcium supplements and concurrent HRT.

The daily dose taken was generally in excess of the RDI and ranged from 100–5000 mg. More specifically, one study found that for each 100 mg increment in dietary vitamin C intake there was an associated increase of 0.017 g/cm^2 in BMD (femoral neck and total hip), and for those women with calcium intakes above 500 mg/day the increment increased to 0.019 g/cm^2 in BMD per 100 mg vitamin C.

A recent Australian study of 533 randomly selected women determined that vitamin C supplements may suppress bone resorption in nonsmoking postmenopausal women (Pasco et al 2006).

In contrast to these results, no effect on BMD was observed for dietary or supplemental vitamin C in the Women's Health Initiative Observational Study and Clinical Trial, which involved 11,068 women aged 50–79 years (Wolf et al 2005). However, a significant beneficial interaction was observed between total vitamin C and HRT on total-body, femoral neck, spine and total-hip BMD.

Animal studies have detected an improved healing response in bone fractures with supplemental vitamin C, suggesting a further role in fracture healing (Yilmaz et al 2001).

Sports

Vitamin C supplementation is often used by athletes in order to improve recovery, restore immune responses, enhance wound healing, and counteract oxidative stress and changes to adrenal hormones and inflammatory responses. It is often taken together with other antioxidant vitamins and minerals, such as vitamin E and zinc. One placebo-controlled study has shown that 20 mg of ascorbic acid twice daily over 14 days has some modest beneficial effects on recovery from unaccustomed exercise (Thompson et al 2001); however, no studies have reported improved performance for vitamin C supplementation.

Prevention of post-endurance-exercise infections

Athletes often use vitamin C supplements to prevent infections, as strenuous training and physiological stress appear to increase the body's need for vitamin C to a level above the usual RDI (Schwenk & Costley 2002). Additionally, the risk of infection after an intense aerobic training session or competition (such as a marathon) is increased (Jeurissen et al 2003).

A 2004 Cochrane Review that analysed results from six trials involving a total of 642 marathon runners, skiers and soldiers on subarctic exercises found regular vitamin C supplementation significantly reduced the incidence of the common cold, supporting its use in this population (Douglas et al 2004).

Alterations to neurotransmitters and adrenal hormone

Several studies have been conducted with ultramarathon runners to investigate whether vitamin C supplementation, usually in doses of 1500 mg/day, is able to restore exercise-induced changes to neurotransmitters, adrenal hormones or inflammatory responses (Nieman et al 2000, Peters et al 2001a, Peters et al 2001b). Overall, it appears that high-dose vitamin C supplements taken at least 7 days before racing does have some effect.

One study involving 45 ultra-marathon runners found that doses of 1500 mg vitamin C taken for 7 days before the race, on the day of the race and for 2 days following the race significantly attenuated exercise-induced elevations in cortisol, adrenaline and IL-10 and IL-1 receptor antagonist levels compared with a placebo (Peters et al 2001a); however, the effect was transient.

Male infertility

A relationship between infertility and the generation of ROS has been established and extensively studied. Alterations in the testicular microenvironment and haemodynamics can increase production of ROS and/or decrease local antioxidant capacity, resulting in generation of excessive oxygen species (OS). A large number of studies have elucidated the effects of increased OS in the serum, semen and testicular tissues of patients.

Vitamin C (ascorbic acid), a major antioxidant found in extracellular fluid, is present in seminal fluid at a high concentration compared with that in blood plasma (364 versus 40 μM) and is present in detectable amounts in sperm (Patel & Sigman 2008). In infertile men, vitamin C has been found in reduced quantity in the seminal plasma (Lewis et al 1997). An association between oxidative stress and sperm DNA fragmentation has been identified and has led to studies looking for changes in semen DNA fragmentation as an outcome rather than just changes in semen parameters.

A review of the literature reveals that interventional studies have produced promising but inconsistent results and incomplete reporting of study outcomes. Sometimes changes to semen parameters are noted, but there is little or no information about successful pregnancies or characteristics of the study population, thereby hindering accurate interpretation of results. Clearly further research is required to better evaluate the effects of vitamin C in male fertility.

An RCT of 75 fertile, heavy smokers compared placebo to two different doses of vitamin C (200 mg and 1000 mg) and found that both supplemented groups experienced a significant improvement in sperm concentration, morphology and viability (Dawson et al 1992).

A randomised, placebo-controlled trial found that treatment with oral vitamin C and E of men with unexplained infertility associated with elevated sperm DNA fragmentation led to decreased DNA fragmentation without a change in semen parameters (Greco et al 2005b).

In an uncontrolled study of 38 men with an elevated percentage of fragmented spermatozoa (R 15%) and one prior failed intracytoplasmic sperm injection (ICSI) attempt, oral supplementation with vitamins E and C demonstrated a significant improvement in pregnancy rate (48.2% versus 6.9%) and implantation rate (19.6% versus 2.2%) when compared with their prior ICSI attempt (Greco et al 2005a).

Adjunct therapy for haemodialysis patients

Recent research highlights that vitamin C can potentiate the mobilisation of iron from inert tissue stores, and facilitates the incorporation of iron into protoporphyrin in haemodialysis patients being treated with epoetin. Eighteen published studies in the past decade have addressed this issue (Attallah et al 2006, Chan et al 2005, Deira et al 2003, Gastaldello et al 1995, Giancaspro et al 2000, Hörl 1999, Keven et al 2003, Lin CL et al 2003, Macdougall 1999, Mydlik et al 2003, Nguyen 2004, Sezer et al 2002, Taji et al 2004, Tarng & Huang 1998, Tarng et al 1999a, Tarng et al 1999b,Tarng et al 2004, Tovbin et al 2000).

Administration of intravenous vitamin C to haemodialysis patients with functional iron deficiency may promote better anaemia control and iron utilisation and has also been used successfully in patients with iron overload (Tarng & Huang 1998, Tarng et al 1999a, Tarng et al 1999b).

OTHER USES

Vitamin C is used for numerous indications, although many have not been significantly studied, such as irritable bowel syndrome, osteoarthritis, menopausal hot flushes, cervical dysplasia, prevention of Alzheimer's dementia, allergies, treatment of lead toxicity and reducing delayed-onset muscle soreness.

Vitamin C supplements have also been used as part of antioxidant combination therapy in HIV and in heroin withdrawal. Preliminary research has shown that some antioxidant combinations reduce oxidative stress (Jaruga et al 2002), induce immunological and virological effects that might be of therapeutic value (Muller et al 2000) and produce a trend towards a reduction in viral load in HIV (Allard et al 1998). High doses of oral ascorbic acid and vitamin E may ameliorate the withdrawal syndrome of heroin addicts after 4 weeks' treatment, according to one study (Evangelou et al 2000).

DOSAGE RANGE

Australian and New Zealand RDI

- Children
  - < 8 years: 35 mg.
  - 9–19 years: 40 mg.
- Adults
  - >19 years: 45 mg.
- Pregnancy
  - < 19 years: 55 mg.
  - > 19 years: 60 mg.
- Lactation
  - <19 years: 80 mg.
  - >19 years: 85 mg.

Deficiency

- 100 mg taken 3–5 times daily until 4000 mg has been administered, followed by a maintenance dose of 100 mg/day and encouragement to eat a diet with fresh fruit and vegetables.
- In cases of acute infection, CAM practitioners frequently recommend vitamin C in doses of 1000 g (or more), to be taken in divided doses every few hours until loose bowels are experienced, otherwise known as 'bowel tolerance'. The rationale behind this dosage regimen is that body requirements during infection are dramatically increased, and not only does high-dose vitamin C meet these needs, but also maximum vitamin C absorption is attained when it is taken in divided doses rather than one large amount.

According to clinical studies

- Asthma: 500–2000 mg before exercise.
- Cancer: 10–100 g/day IV.
- Cardiovascular disease prevention: up to 1000 mg/day long term.
- Bone mineral density: 750 mg/day long term.
- Cataract protection: 500 mg/day long term.
- Diabetes: 0.5–3 g/day long term.
- Histamine-lowering effects: 250 mg to 2 g/day for several weeks.
- Respiratory infection: 1–2 g/day.
- Sunburn protection: oral vitamin C (2000 mg/day) in combination with vitamin E (1000 IU/day).
- Urinary acidification: 4–12 g taken in divided doses every 4 hours.

ADVERSE REACTIONS

Adverse effects of oral vitamin C include loose bowels and diarrhoea with high-dose supplements; however, the dose at which this occurs varies between individuals and also varies for each individual at different times.

SIGNIFICANT INTERACTIONS

Aluminium-based antacids

Vitamin C increases the amount of aluminium absorbed. Separate doses by at least 2 hours.

Aspirin

Aspirin may interfere with both absorption and cellular uptake mechanisms for vitamin C, thereby increasing vitamin C requirements (observed in animal and human studies). Increased vitamin C intake may be required with long-term therapy (Basu 1982).

Chitosan

According to a preliminary study in rats, taking vitamin C in combination with chitosan might provide additional benefit in lowering cholesterol. Potentially beneficial interaction.

Cisplatin

Vitamin C enhanced the antitumour activity of cisplatin in several in vitro tests (Abdel-Latif et al 2005, Sarna & Bhola 1993, Reddy et al 2001) and reduced drug toxicity in experimental models (Giri et al 1998, Greggi Antunes et al 2000). Potentially beneficial but difficult to assess.

Corticosteroids

Corticosteroids may increase the requirement for vitamin C based on in vitro and in vivo data (Chowdhury & Kapil 1984, Levine & Pollard 1983). Increased intake may be required with long-term drug therapy.

Cyanocobalamin
Vitamin C can reduce absorption of cyanocobalamin. Separate doses by at least 2 hours.

Cyclophosphamide
Vitamin C enhanced the therapeutic drug effect in vivo (Lamson & Brignall 2000). Potentially beneficial but difficult to assess.

Doxorubicin
Vitamin C enhanced the therapeutic drug effect and reduced drug toxicity in vivo (Lamson & Brignall 2000). Potentially beneficial but difficult to assess.

Etoposide
Vitamin C enhanced the antitumor activity of etoposide in vitro (Reddy et al 2001). Potentially beneficial but difficult to assess.

Fluorouracil
Vitamin C enhanced the antitumour activity of 5-fluorouracil in vitro and in vivo (Abdel-Latif et al 2005, Nagy et al 2003). Potentially beneficial but difficult to assess.

Iron
Vitamin C increases the absorption of iron. Potentially beneficial interaction.

L-Dopa
A case report of co-administration with vitamin C suggests this may reduce drug side effects (Sacks & Simpson 1975). Beneficial interaction.

Tamoxifen
Vitamin C enhanced the antitumour activity in vitro (Lamson & Brignall 2000). Potentially beneficial but difficult to assess.

Vincristine
Vitamin C enhanced the drug's effect in vivo (Lamson & Brignall 2000). Potentially beneficial but difficult to assess.

PS-341 (Bortezomib, Velcade)
This is a proteasome inhibitor approved by the USFDA for the treatment of patients with relapsed multiple myeloma. Vitamin C inactivated drug activity in vitro (Zou et al 2006). Avoid until safety can be established.

CONTRAINDICATIONS AND PRECAUTIONS
In patients who are sensitive to iron overload, vitamin C supplementation may exacerbate iron toxicity by mobilising iron reserves. As such, vitamin C supplementation should be used with caution by people with erythrocyte glucose-6-phosphate dehydrogenase deficiency, haemochromatosis, thalassaemia major or sideroblastic anaemia.

Intravenous vitamin C
A dose-response study involving patients with solid tumours receiving high-dose IV vitamin C found virtually all the side effects that occurred were consistent with the side effects attending the rapid infusion of any high-osmolarity solution. The symptoms were preventable by encouraging patients to drink fluids before and during the infusion. Indeed, rather than provoking fluid overload, ascorbic acid acted like an osmotic diuretic which could induce volume depletion if patients did not compensate by increasing their voluntary fluid intake. Therefore, contraindications to the infusion of very-high-osmolarity ascorbic acid infusions are the same as for other osmotic diuretics: anuria, dehydration, severe pulmonary congestion or pulmonary oedema and a fixed low cardiac output (Hoffer et al 2008).

Clinical note — Does vitamin C interact with the OCP?
In 1981 a case was reported of a woman who had experienced heavy breakthrough bleeding as a result of stopping vitamin C supplementation while taking the oral contraceptive pill (Morris et al 1981). At the time, it was suspected that vitamin C in high doses increases the bioavailability of oestrogen and raises blood concentrations due to competition for sulfation (resulting in reduced drug metabolism) (Back & Orme 1990). Therefore, ceasing supplement use would have the opposite effect and potentially cause breakthrough bleeding, as reported in this case. Since then, further investigation has been conducted to investigate whether this interaction is clinically significant. In 1993 a placebo-controlled study was conducted with 37 women and found that 1000 mg of vitamin C does not lead to an increased systemic bioavailability of ethinyl oestradiol, and therefore the purported interaction is unlikely to be of any clinical importance (Zamah et al 1993).

Laboratory tests
Supplemental vitamin C can affect the results of numerous laboratory tests and should be stopped prior to:
- carbamazepine
- lactate dehydrogenase
- serum AST
- serum bicarbonate
- serum cholesterol
- serum creatinine
- serum creatine kinase
- serum HbA_{1c}
- serum phosphate
- serum triglycerides
- serum urea nitrogen
- stool guiac
- theophylline
- urine 17-hydroxy corticosteroids
- urine 17-ketosteroids
- urine amphetamine
- urine and serum bilirubin
- urine and serum glucose
- urine and serum uric acid
- urine barbiturate
- urine beta-hydroxybutyrate

- urine iodide
- urine oxalate
- urine paracetamol
- urine protein.

PREGNANCY USE

Vitamin C is safe in pregnancy.

PATIENTS' FAQs

What will this vitamin do for me?

Vitamin C is necessary for health and wellbeing. Supplements have also been used for a variety of indications and in some cases shown to have benefits.

When will it start to work?

Studies have found that dietary or supplemental vitamin C may be required for at least 10 years before protection against heart disease or cancer incidence is detected. However, other benefits may be experienced more quickly, depending on the dose used and indication.

Are there any safety issues?

Vitamin C is considered very safe, although high doses may induce reversible loose bowels or diarrhoea. Supplements should be taken only under medical supervision by people with erythrocyte glucose-6-phosphate dehydrogenase deficiency, haemochromatosis, thalassaemia or sideroblastic anaemia.

Clinical note — Is the kidney stone risk overstated?

Most kidney stones consist of calcium oxalate, and higher urinary oxalate increases the risk of calcium oxalate nephrolithiasis (Taylor & Curhan 2007). Four mechanisms have been identified that account for increased oxalate excretion: increased dietary intake of oxalate, abnormally increased intestinal absorption of oxalic acid, a deficiency of oxalate-degrading bacteria (in particular *Oxalobacter formigenes*) and increased endogenous production of oxalate. Vitamins C and B_6 are both involved in the metabolic pathway of oxalate. While 40% of dietary vitamin C undergoes a non-enzymatic conversion to oxalate, vitamin B_6 has the opposite effect and metabolises oxalate (Gill & Rose 1985). Since vitamin C has been shown in some (but not all) studies to increase urinary oxalate, researchers speculated that it might have a detrimental role in increasing the risk of kidney stone formation.

Reports of a possible link between ascorbic acid and kidney stones started to appear in the literature in the 1980s (Griffith et al 1986, Power et al 1984). These findings have been challenged by several studies carried out in humans and in experimental animals since that time. In 1994, researchers discovered that vitamin C (in doses as high as 10 g/day) does not increase the amount of oxalate produced in the body in non-stone forming people (Wandzilak et al 1994). Instead, urine tests used to detect oxalate levels were actually detecting oxalate formed by the conversion of ascorbate during the test procedure. As such, urine oxalate levels tested by this method do not genuinely represent in vivo oxalate when ascorbate is involved. Three studies that followed found no association between vitamin C intake and kidney stone risk. Two prospective studies of more than 85,000 women and 45,000 men found that doses ranging from less than 250 mg/day to more than 1500 mg/day taken over 6–14 years did not correlate with occurrence of kidney stones (Curhan et al 1996, 1999). The third was a controlled study measuring oxalate excretion and several other biochemical and physicochemical risk factors associated with calcium oxalate urolithiasis (Auer et al 1998, Curhan et al 1996, Curhan et al 1999).

Based on the available evidence, it appears unlikely that vitamin C supplements increase the risk of nephrolithiasis in the general population, particularly if they are used in the short to medium term.

PRACTICE POINTS/PATIENT COUNSELLING

- Vitamin C is an essential nutrient for humans, as we are one of the few animal species that cannot synthesise it endogenously.
- Although vitamin C is found widely in fruit and vegetables, up to 100% can be destroyed during cooking and storing, as it is sensitive to light, heat, oxygen and alkali.
- Although frank deficiency is uncommon in Western countries, marginal deficiency states are not uncommon, particularly in young children fed exclusively on cow's milk for a prolonged period, the institutionalised or isolated elderly, chronic alcoholics, the urban poor and cigarette smokers.
- Vitamin C is an antioxidant and is involved in a myriad of biochemical processes in the body, such as neurotransmitter and hormone synthesis, maintenance of connective tissue, immune function and adrenal function.
- Many studies have found a protective effect for dietary vitamin C intake on cardiovascular disease and cancer incidence, emphasising the importance of adequate dietary intake of fresh fruit and vegetables. Positive effects have also been detected for bone density and cataract incidence.
- Oral vitamin C supplements have been investigated in many different conditions. Positive results have been obtained in some of these studies, such as for reducing duration of the common cold, coronary heart disease prevention, prevention of several cardiovascular diseases and bone mineral density. Results in cancer treatment remain controversial for oral supplements.
- New research shows that long-term supplements do not increase the risk of kidney stones and do not interact with oral contraceptives.

Vitamin D

HISTORICAL NOTE Vitamin D was identified as a nutrient in the early 1900s, when it was first realised that cod liver oil had an antirachitic effect in infants.

BACKGROUND AND RELEVANT PHARMACOKINETICS

The name 'vitamin D' actually refers to several related fat-soluble vitamin variants, all of which are sterol (cholesterol-like) substances. Cholecalciferol (D_3) is the form found in animal products and fish oils, whereas ergocalciferol (D_2) is the major synthetic form of provitamin D typically found in supplements and fortified foods; however, other forms also exist. These ingested forms have 50–80% bioavailability and enter the lymphatic circulation from the small intestine following emulsification by bile salts. In the liver and kidneys, both D_2 and D_3 are converted to D's major circulating forms: 25-hydroxycholecalciferol (inactive) — 25(OH)D and 1,25-dihydroxycholecalciferol (active) — $1,25(OH)_2D$.

Vitamin D (D_3) is also produced in the body through the conversion of a cholesterol-based precursor, 7-dehydrocholesterol, which is produced in the sebaceous glands of the skin. Exposure to sunlight (UVB) converts this precursor into cholecalciferol over a 2–3 day period. Prolonged exposure to UVB can inactivate some of the newly formed vitamin D and its precursors, so that eventually a state of equilibrium is reached between vitamin D synthesis and catabolism. Therefore, short periods of sun exposure are considered more efficacious than long periods (Working Group 2005). Some vitamin D is stored in adipose tissue and can be mobilised during periods when exposure to sunlight is reduced or shortages develop (Nowson & Margerison 2002). Vitamin D and its metabolites are primarily excreted through bile, and the degraded active form is removed via the kidney. Losses are believed to be minor, owing to both reabsorption of vitamin D derivatives via the enterohepatic recirculation and limited filtration at the kidneys (Kohlmeier 2003). Parathyroid hormone (PTH), calcium, phosphorus and magnesium are involved in the regulation of vitamin D metabolism.

Traditionally associated with bone health, the identification of vitamin D receptors (VDR) on a large and diverse number of cells has precipitated significant reconsideration of this nutrient (Dusso et al 2005, Holick 2004, Holick 2006). Consequently, we now understand that vitamin D possesses two distinct action pathways dependent upon the site of bioactivation (Dusso et al 2005, Holick 2006). Renal hydroxylation of 25(OH)D produces $1,25(OH)_2D$, primarily responsible for its traditional endocrine actions.

Extrarenal bioactivation, by immune, prostate, breast, colon, beta and skin cells, however, results in non-genomic responses, characterised as autocrine rather than endocrine effects (Dusso et al 2005, Kemmis et al 2006, Holick 2006). Production of $1,25(OH)_2D$ at these sites does not fall under the same tight regulatory control as renal 1-alpha-hydroxylase (Dusso et al 2005, Kemmis et al 2006). This means that increasing concentrations of 25(OH)D provide a substrate for extrarenal bioactivation, with the rate of conversion mainly reliant upon local factors such as cytokines (Holick 2005b, Lips 2006).

Is vitamin D really a vitamin?

Many characteristics of the vitamin D molecules vary substantially from the orthodox definition of a vitamin (Dusso et al 2005, NHMRC 2006, Vieth 2006) in that they:

- are not essential in the diet of all individuals, given adequate sun exposure (Dusso et al 2005, Nowson & Margerison 2001)
- are structurally steroid derivatives (Gropper et al 2009)
- are inherently biologically inactive and require hydroxylation to produce the active form (Holick 2005b, Kemmis et al 2006)
- produce $1,25\ (OH)_2D$, which is a steroidal hormone (Dusso et al 2005)
- require VDR on cell surfaces, a member of the steroid receptor superfamily, to convey most if not all of their actions (Dusso et al 2005, Holick 2004).

These discoveries and others have precipitated a revolution in vitamin D research over the last decade (Dusso et al 2005, Holick 2004, Holick 2005b).

CHEMICAL COMPONENTS

Cholecalciferol (D_3) is considered to be the most important dietary form and is identical to the form produced in the body. Ergocalciferol (D_2) is produced by fungi and yeasts and is rare in the diet, but a common supplemental/fortificant form (Nowson & Margerison 2002). Some authors suggest that D_2 should not be classified as a nutrient, given that it has no natural place in human biology (Trang et al 1998, Vieth 2006) and, while both D_2 and D_3 were previously considered to be equipotent as supplements (FAO/WHO 2002, Nowson & Margerison 2002, Wahlqvist 2002), recent exploration of this issue points to marked discrepancies in favour of D_3 (see box). D_2 also comes under the names 1-alpha-OHD_2, calcifediol, calciferol, dihydrotachysterol (DHT), ergocalciferolum and ergosterol; D_3 may be referred to as 1-alpha-OHD_3, alfacalcidiol, calcitriol or rocaltrol (Micromedex 2003).

Quantification of any of the vitamin D forms is expressed in either International Units (IU) or micrograms. The conversion is: 1 μg = 40 IU.

Are all vitamin D forms alike?

Coincident with the recognition of 25(OH)D as the key marker of individual vitamin D status, the ability of cholecalciferol (D_3) and ergocalciferol (D_2) to increase serum levels of this marker have been compared (Trang et al 1998). Results from these studies reveal a 70% greater increase in serum 25(OH)D in response to cholecalciferol (D_3). Hypothesised reasons for this difference are based upon the distinct metabolic handling of the two different forms. D_3 demonstrates higher affinity for D binding protein (DBP), making it less likely to be excreted in bile (Armas et al 2004, Dusso et al 2005), produces more potent metabolites and is converted into 25(OH)D up to five times faster than D_2 (FSANZ 2007, Houghton & Vieth 2006, Trang et al 1998). The results of another study showed that serum 25(OH)D increases in response to D_2 supplementation were not sustained, and in fact fell below baseline values over 14 days, while the serum levels of those supplemented with D_3 continued to rise throughout the same period (Armas et al 2004). In addition to these concerns, the stability and purity of D_2 preparations are questionable (Houghton & Vieth 2006).

These findings have major ramifications for the interpretation of vitamin D research and the clinical implementation of such protocols. Every piece of vitamin D research must now be considered in the light of the supplemental form used. Clinically D_3's improved potency translates to significantly lower dose requirements, in the vicinity of 2.5–10 times less) (FSANZ 2007, Houghton & Vieth 2006), compared with a D_2-based product (Glendenning 2002).

FOOD SOURCES

Small amounts are found in fatty fish, such as herring, salmon, tuna and sardines, beef and liver, butter, eggs and fortified foods such as margarine and milk (Gropper et al 2009). Cod liver oil is also a good source. Notably, meat products also contain some 25(OH)D, which is five times more active than D_3 (Nowson & Margerison 2001); however, the vitamin D content of all animal products is dependent upon the individual animal's vitamin D status and the use of fortified feed (Mattila et al 2004). There is therefore concern that as a consequence of modern agricultural and aquacultural practices vitamin D content is in decline, as demonstrated by a recent study which revealed a 75% decrease in the vitamin D content of farmed compared to wild salmon (Lu et al 2007). Naturally occurring D_2 is found only in mushrooms.

Current vitamin D fortification practices in Australia permit the use of either D_2 or D_3 without distinction and include both mandatory fortification (edible oil spreads and table margarine) and voluntary fortification (modified and skim milks, powdered milk, yoghurt, cheese, butter, legume- and cereal-based analogue beverages) (FSANZ 2007, Nowson & Margerison 2001). Australian diet studies reveal that fortified margarine and edible oil spreads make the largest single contribution to vitamin D consumption (28–53%) (NHMRC 2006, Nowson & Margerison 2001). A recent Australian study found that average dietary consumption of vitamin D was 1.2 μg/day and that only 7.9% of this sample took vitamin D supplements (van der Mei et al 2007).

DEFICIENCY SIGNS AND SYMPTOMS

Although the traditional understanding of hypovitaminosis D revolves around its critical role in calcium metabolism, the extensive presence of VDR throughout the body is providing the impetus for further research into actions, deficiency states and therapeutic applications (Gropper et al 2009).

Primary deficiency

Unlike many other vitamins, vitamin D is not only ingested through the diet but also produced and stored in the body. As such, endogenous production, which is reliant on adequate exposure to sunlight, will greatly influence whether deficiency states develop. It has been estimated that exposing the skin to UVB radiation produces approximately 90% of the vitamin D_3 (cholecalciferol) that is bioavailable in the body. Currently, the NHMRC reports that it is almost impossible to get sufficient vitamin D from dietary sources alone, stressing the importance of UVB exposure (NHMRC 2006).

Deficiency more prevalent than once thought

Inadequate vitamin D among Australians is now recognised as a substantial concern, given the significant percentage demonstrating a combination of poor dietary intake and inadequate sun exposure, according to the 2005 position statement released by the Working Group of the Australian and New Zealand Bone and Mineral Society, Endocrine Society of Australia and Osteoporosis Australia.

Ongoing epidemiological research in Australia supports this view and has identified the wider community at risk of mild deficiency, with the results of numerous studies supporting this preposition. Using a cut-off of ≤ 50 nmol/L for serum 25(OH)D, vitamin D insufficiency has been found to affect > 40% of healthy adults in Queensland (Kimlin et al 2007, van der Mei et al 2007), > 65% Tasmanians (van der Mei et al 2007) and up to 74% of general medical inpatients (Chatfield et al 2007) — including 54% of the last group who were taking vitamin D supplements. A study of maternal and neonatal levels in Sydney revealed that 15% of mothers (at 23–32 weeks' gestation) and 11% of neonates met the criteria for overt vitamin D deficiency (≤ 25 nmol/L) (Bowyer et al 2009). These rates increase dramatically if the reference range for optimal serum 25(OH)D is raised, as has been proposed in the scientific literature (Dawson-Hughes et al 2005, Vieth 2001, Vieth 2006). One group of researchers re-analysed population data based on the proposed cut-off of ≤ 80 nmol/L (Dawson-Hughes et al 2005, Heaney 2006, Holick 2005b) and found that 70% of their sample of healthy Australians would, using this definition, be below optimal (van der Mei et al 2007).

Factors associated with lower 25(OH)D levels in Australia include:

- seasonal effects, with winter–early spring demonstrating peak incidence (Bowyer et al 2009, Chatfield et al 2007, Kimlin et al 2007, McGillivray et al 2007, van der Mei et al 2007)
- increasing latitude (van der Mei et al 2007)
- increasing skin pigmentation (Kimlin et al 2007), with one study calculating an odds ratio of 2.7 for dark skin (Bowyer et al 2009)
- non-Australian birthplace: odds ratio (OR) 2.2 (Erbas et al 2008)
- hospitalisation, and institutionalisation and age (Bruyere et al 2009).

The institutionalised elderly are of particular concern, as their exposure to sunlight is often restricted and they have an estimated twofold reduction in capacity of the skin to produce D_3 (Wilson et al 1991), compromised final conversion in the kidneys, reduced tissue response and further reductions to calcium absorption independent of these pathways (Bouillon et al 1997, FAO/WHO 2002). The increasing risk with age is clearly demonstrated by the results of a Tasmanian study, which revealed that although only 8% of 8-year-olds were considered vitamin D deficient, deficiency escalated with increasing age to peak at 85% for people aged 60 years (RACGP 2003).

At the other end of the age spectrum, a 2-year surveillance of infants presenting with vitamin-D-deficiency-related problems at the Monash Medical Centre in Clayton, Victoria, found that the 13 infants admitted to hospital all had migrant parents and were predominantly or exclusively breastfed (Pillow et al 1995). This is a dangerous combination, with dark-skinned migrants at a significantly greater risk of deficiency (Bowyer et al 2009, Erbas et al 2008), particularly women who are veiled (OR 21.7) (Bowyer et al 2009, Grover & Morley 2001, Nowson & Margerison 2002, Wigg et al 2006), and breastmilk recognised as a poor source of vitamin D (Andiran et al 2002). Australian research demonstrates that recently immigrated infants or first-generation offspring of immigrant parents, especially Indian, Middle Eastern, African and Polynesian, are a key at-risk group: 40% of infants aged 4–12 months were found to be deficient (Nozza & Rodda 2001, Robinson et al 2006) and 87% of sampled east-African children (0–17 years) living in Melbourne recorded serum 25(OH)D levels ≤ 50 nmol/L (McGillivray et al 2007).

Other populations at risk include obese individuals (Arunabh et al 2003, Blum et al 2008, Harris & Dawson-Hughes 2007), psychiatric patients (Berk et al 2007) and individuals with an intellectual disability (estimated deficiency prevalence 50–60%) (Vanlint et al 2008).

Secondary deficiency

Malabsorption states such as coeliac disease, Crohn's disease, gastrectomy, intestinal resection, chronic cholestasis, cystic fibrosis and pancreatic disorders

Clinical note — The vitamin D dilemma

Between 80% and 100% of our vitamin D needs can be met through adequate sun exposure, with dietary intake only required to meet the shortfall (Nowson & Margerison 2001, Nowson & Margerison 2002, Samanek et al 2006). Quantifying this shortfall, however, is complex and individualistic, as multiple variables influence the rate of endogenous production, such as age, season, latitude, time of day, part of body exposed to sunlight and use of sunscreen. Researchers estimate that full-body sun exposure in Australia, sufficient to induce mild erythema, is equivalent to consuming 15,000 IU orally (Working Group 2005). Hence, we have the dilemma: while the majority of public health messages continue to promote sun-protection, there is growing media coverage of the negatives associated with this and advocacy for exposure to UVB in order to prevent vitamin D deficiency (Scully et al 2008). The successful 'Slip slop slap' campaign in Australia, which encourages covering up and reduced sun exposure, appears at odds with the vitamin D message and may have put many Australians at risk of poor vitamin D status. Recent Australian research concurs with this, indicating that the public health message battle is currently being won by 'sun protection', with only 15% of surveyed Australians agreeing with the statement that 'sun protection may result in not having enough vitamin D' (Janda et al 2007).

Clearly, revision of the current public health messages regarding both vitamin D and safe sunlight exposure has been required for some time. In response, work has been undertaken to develop a message of compromise (Nowson & Margerison 2002, Working Group 2005), and the development of a 'vitamin D index', similar to a UV index, has been proposed (van der Mei et al 2007). Recent evidence from a study by Samanek et al (2006) supports the concept that safe sun exposure can yield vitamin D adequacy. Their research concluded that from October to March only 10–15 minutes of unprotected exposure to 15% of the body outside of the hours of 10 am to 3 pm was sufficient; however, during other seasons, up to 1 hour of exposure was required. In addition to this, the authors themselves acknowledge that calculations were based on existing serum values, which have been widely contested by other researchers (Gomez et al 2003). In view of some of these concerns, the new NHMRC vitamin guidelines released in 2006 are now recommending an increased AI of vitamin D, particularly for adults aged over 50 years. It also suggests varying lengths of time for sun exposure for different skin types in order to achieve adequate levels. Whether these initiatives are sufficient to prevent deficiency in the community remains to be seen.

increase the risk of deficiency (Hendler & Rorvik 2001, Kumar & Clark 2002).

The use of certain anticonvulsants and chronic administration of glucocorticoids increase the risk of vitamin D deficiency. Several rare hereditary forms of rickets develop because the body cannot process (metabolise) vitamin D normally (Beers & Berkow 2003). Chronic liver disease will obstruct the first hydroxylation reaction, and end-stage kidney disease results in negligible conversion of 25-OHD into 1,25-OHD (Kumar & Clark 2002, Micromedex 2003). One large study also demonstrated that levels of serum 25-OHD are inversely correlated with percentage of body fat and, as such, morbidly obese individuals have increased requirements (Arunabh et al 2003).

Signs and symptoms of deficiency

The previously determined serum concentrations of 25-OHD believed to be indicative of deficiency (< 20–25 nmol/L) are considered outdated (Gomez et al 2003). It is now apparent that much higher concentrations, deemed 'suboptimal' status, have deleterious effects (Dawson-Hughes et al 2005, Heaney 2006, Holick 2005b, Nowson & Margerison 2002). Indications of deficiency include:

- alopecia with dilated hair follicles and dermal cysts (Dusso et al 2005)
- anaemia, decreased bone cellularity and extramedullary erythopoiesis (Brown et al 1999)
- cardiomegaly (Dusso et al 2005, Holick 2005b)
- chronic fatigue syndrome (deficiency may be misdiagnosed as this) (Holick 2004, Schinchuk & Holick 2007)
- chronic lower back pain (Al Faraj & Al Mutairi 2003)
- excess PTH secretion and parathyroid hyperplasia
- fibromyalgia (estimated that 40–60% of patients diagnosed with this condition are actually suffering from vitamin D deficiency) (Holick 2004, Holick 2005b, Schinchuk & Holick 2007)
- hypertension (Dusso et al 2005, Forman et al 2007, Holick 2005b)
- impaired glucose-mediated insulin secretion (Brown et al 1999)
- increased risk of fracture in the elderly (not limited to vitamin D's influence on bone mass)
- increased susceptibility to mycobacterial and viral infections (Dusso et al 2005)
- peripheral vascular disease with claudication (may be misdiagnosed or confounding factor) (Holick 2005b)
- rickets and osteomalacia
- osteopenia and osteoporosis
- sarcopenia — skeletal muscle weakness and atrophy (Dusso et al 2005, Visser et al 2003)
- stunting.

Deficiency also significantly increases the risk of:

- autoimmunity, including multiple sclerosis (including increased severity of preexisting cases) (Dusso et al 2005, Holick 2004), diabetes type 1 (Holick 2006) and inflammatory bowel disease (Holick 2004)
- cancer — breast, prostate, colon and skin cancers are among the 20 different cancer types demonstrating an inverse relationship with vitamin D levels (Holick 2004)
- heart failure in CVD patients (Holick 2005b)
- non-insulin-dependent diabetes mellitus in high-risk populations — some studies (Pittas et al 2007) but not all (Reis et al 2007) show positive association
- preeclampsia — particularly if hypovitaminosis D is present at < 22 weeks (Bodnar et al 2007).

MAIN ACTIONS

Whereas vitamin D is considered a fat-soluble vitamin, its active metabolite $1,25(OH)_2D_3$ is considered to be more like a steroid hormone, because it can be produced by the body and moves through the systemic circulation to reach target tissues via receptors both at the cell membrane and at the nuclear receptor proteins. Vitamin D possesses two distinct action pathways dependent upon the site of bioactivation (Dusso et al 2005, Holick 2006). Renal hydroxylation of 25(OH)D produces $1,25(OH)_2D$, primarily responsible for its traditional endocrine actions mentioned, as well as playing a role in intestinal detoxification (Kutuzova & DeLuca 2007), healthy insulin secretion (Brown et al 1999, Dusso et al 2005, Mathieu & Badenhoop 2005) and blood pressure control, via inhibition of rennin production and blunting cardiomyocyte hypertrophy (Dusso et al 2005, Holick 2005b, Simpson et al 2007).

Extrarenal bioactivation, by immune, prostate, breast, colon, beta and skin cells, however, results in non-genomic responses characterised as autocrine rather than endocrine effects (Dusso et al 2005, Kemmis et al 2006, Holick 2006). These autocrine effects include controlling immune function (especially anti-inflammatory), cellular growth, maturation, differentiation and apoptosis (Dusso et al 2005, Kemmis et al 2006, Lips 2006, Holick 2005b) as well as photoprotection (Dixon et al 2007), explaining vitamin D's emerging role in immune function and cancer prevention.

Regulation of calcium and phosphorus levels

In conjunction with PTH, which is released under conditions of low calcium levels, vitamin D can stimulate calcium and phosphorus absorption in the intestines, reabsorption in the kidneys and release of calcium from the bones back into the blood. $1,25-(OH)_2D_3$ in turn is regulated by PTH, calcium, phosphorus and $1,25-(OH)_2D_3$ itself (Wahlqvist 2002). To achieve the maximal efficiency of vitamin D-induced intestinal calcium transport, the serum 25(OH)D concentrations must be at least 78 nmol/L (30 ng/mL). In deficiency, intestinal absorption of calcium can be halved in adults (Holick 2004).

Modelling and remodelling of bone

Besides influencing bone by maintaining calcium and phosphorus homeostasis, vitamin D may also contribute to bone health in other ways.

One pathway involves binding of $1,25\ (OH)_2D_3$ to DNA to promote transcription of specific mRNA, which codes for osteocalcin. Osteocalcin

is then secreted by the osteoblasts, which bind calcium in new bone (Gropper et al 2009). Vitamin D also appears to play a role in oestrogen biosynthesis by increasing expression of the aromatase enzyme gene. It has demonstrated a synergistic effect in select tissues with the phyto-oestrogen genistein, with co-administration leading to a prolonged half-life of active vitamin D (Harkness & Bonny 2005, Swami et al 2005).

Cell differentiation, proliferation and growth

Some of the actions already described are the result of the vitamin's capacity to affect cell differentiation, proliferation and growth in many tissues (e.g. differentiation of stem cells into osteoclasts to facilitate bone resorption). Alternatively, 1,25-$(OH)_2D_3$ can inhibit proliferation in many cells, including lymphocytes, keratinocytes, mammary, cardiac and both skeletal and smooth muscle cells. This ability has led to its investigation as a treatment for proliferative disorders such as cancer (Brown et al 1999, Gropper et al 2009, Kohlmeier 2003).

Reduction of PTH and regulation of growth of the parathyroid gland

Although PTH regulates the levels of 1,25-$(OH)_2D$, its secretion is regulated by vitamin D, calcium and phosphorus. In deficiency, hypersecretion of this hormone can cause excessive growth of the parathyroid gland and secondary hyperparathyroidism (Brown et al 1999).

Immunomodulation

Vitamin D enhances the immune system's response to both bacterial and viral agents (Grant 2008c), primarily through promoting differentiation and activity of the macrophages, which means that immune responses can be tailored through the appropriate cell response (Brown et al 1999) but also through the induction of cathelicidin (Maalouf 2008). Vitamin D influences the cytokine production of immune cells, suppressing the release of IL-2, IFN-gamma and TNF-alpha, products of the Th-1 line of cells, thereby reducing the propensity for a range of autoimmune conditions (Thien et al 2005). This reflects its propensity for inhibiting adaptive immunity while potentiating the innate response (Bikle 2008). There is speculation that through this mechanism, vitamin D will promote a Th-2 dominance and may predispose to the atopic diathesis. Supporting evidence comes from two studies that reveal supplementation with vitamin D in early life to be a potential precipitator of allergic disease (Hypponen et al 2001); however, in other scenarios (e.g. autoimmunity) this effect would be considered to be therapeutic (Smolders et al 2008).

OTHER ACTIONS

Our current understanding of the role of vitamin D appears to be only part of the picture. Ongoing discovery of previously unidentified receptors on tissues continues to broaden our understanding of its diverse effects.

Haematopoietic tissues

Vitamin D appears to exert an effect on erythopoiesis and bone cellularity through unknown mechanisms. It has also been shown to inhibit clonal cell proliferation in some leukaemia lines and to promote differentiation (Brown et al 1999).

Muscle

Vitamin D maintains muscle strength and has an effect in skeletal muscle and myocardial function. Although it has been established that skeletal muscles have receptors for vitamin D, the specific actions of this steroid on muscle are largely unknown. Recently a link between fibromyalgia and vitamin D deficiency has been suggested, 40–60% of cases presenting with generalised muscle weakness and pain being estimated as undiagnosed hypovitaminosis (Holick 2004). Through unidentified mechanisms vitamin D exerts a direct effect on the myocardium: 1,25-$(OH)_2D_3$ controls hypertrophy in cardiac monocytes and, together with 25-OHD, improves the left ventricular function in patients with cardiomyopathies (Brown et al 1999).

Pancreas

Vitamin D is essential for normal insulin secretion, as demonstrated in both animals and humans, and vitamin D receptors have been found in pancreatic beta cells, whose function improves following vitamin D repletion (Alemzadeh et al 2008, Mathieu & Badenhoop 2005, Palomer et al 2008). Enhanced insulin synthesis may be due to vitamin D's role in controlling intracellular calcium flux in islet cells which facilitates conversion of proinsulin to insulin, exocytosis of insulin and beta cell glycolysis (Brown et al 1999, Palomer et al 2008). Vitamin D also modulates insulin receptor gene expression (Palomer et al 2008).

Brain

Evidence is emerging about the specific role of vitamin D in the brain. Information to date implicates 1,25$(OH)_2D$ in the biosynthesis of neurotrophic factors, contribution to brain detoxification pathways with increased glutathione and reduced nitric oxide, neuroprotective effects, induction of glioma cell death and involvement in neurotransmitter synthesis, including acetylcholine and the catecholamines (Garcion et al 2002). The vitamin D receptor (VDR) and 1-alpha-hydroxylase activity has been demonstrated in specific brain regions (e.g. the hypothalamus), implying a potential role for vitamin D as a neuroactive hormone (Berk et al 2007, Obradovic et al 2006, Vieth et al 2004). There is also increasing evidence of vitamin D's modulation of several neurotransmitters, such as acetylcholine, catecholamines, serotonin (Jorde et al 2006, Obradovic et al 2006). Preliminary studies in rats have demonstrated an anti-epileptic action (Kalueff & Tuohimaa 2005). Tentative links are being made between the aetiology/pathophysiology of Parkinson's disease and poor vitamin D status (Johnson 2001, Kim et al 2005).

CLINICAL USE

Vitamin D is administered using various routes and can be prescribed as either a supplement or a drug. This review will focus on oral supplementation of D_2 or D_3 only and will not cover the variety of analogues that continue to be extensively studied. For many conditions that appear to require high doses, the race is on to develop and trial pharmaceutical analogues that retain, in particular, the antiproliferative nature of the vitamin, but are low-calcaemic in order to minimise the associated toxicity seen at such doses.

Deficiency states

Frank vitamin D deficiency in infancy or childhood produces rickets, which results from reduced sun exposure, deficient diet or metabolic or malabsorptive diseases. Vitamin D deficiency results in inadequate calcium and phosphorus levels for bone mineralisation (Beers & Berkow 2003). Diagnosis is confirmed with X-ray and serum assay of 25(OH)D. When occurring in adults, it is called osteomalacia, and its first presentation is often as chronic lower back pain (Al Faraj & Al Mutairi 2003).

Defective vitamin D metabolism may be another cause, and consequently deficiency will not respond to standard oral treatment. In this situation, extremely high doses may be required, which should be monitored carefully for toxicity (Beers & Berkow 2003).

Pregnancy and lactation supplementation

Vitamin D appears to be critical both to the musculoskeletal and neurological growth and to the development of the infant. A recent Australian study investigated the well-documented seasonal variation in birth weight to determine the parameters of anthropometric changes associated with this seasonal variation (McGrath et al 2005). Comparison of over 350,000 mean monthly birth weights of neonates at more than 37 weeks' gestation revealed that overall size, length, head size and skinfold thickness all display seasonal variation, but in particular greater limb length occurred with winter/spring births. Earlier animal studies imply that this may be a consequence of hypertrophy of the cartilage growth plates due to prenatal hypovitaminosis D (McGrath et al 2005).

Whether pregnant women require additional supplementation has been investigated in some studies. The Cochrane Controlled Trials Register has assessed only two trials, producing inconsistent results (Mahomed & Gulmezoglu 2000). However, trials involving more than 500 women conducted by Marya et al (1981, 1987), not included in the Cochrane Register review, have demonstrated statistically significant increased fetal birth weight, reduced prevalence of hypocalcaemia and hypophosphataemia, detected in both maternal and cord blood, and reduced blood pressure in non-toxaemic women. Additional evidence suggests a preventative role for a range of autoimmune conditions in the offspring when prenatal vitamin D levels are adequate (Holick 2004).

There is greater consensus regarding the need for vitamin D supplementation during lactation; breast milk is recognised as a poor source of this vitamin and infants are largely dependent on stored vitamin D acquired in utero (Andiran et al 2002).

Children

The optimal regime in relation to both route and dose of vitamin D for at-risk children remains controversial and is based on studies of limited size (Huh & Gordon 2008). The most common recommendation for infants is to supplement with D_2 or D_3 at 1–2000 IU/day and up to 4000 IU/day in children older than 1 year.

Treatment of deficiencies secondary to malabsorptive syndromes

Numerous studies have confirmed a high prevalence (25–75%) of hypovitaminosis D in patients with coeliac disease, Crohn's disease, small bowel resection or cystic fibrosis. A positive correlation between low vitamin D status and clinical consequences, such as reduced bone mineral density (BMD) and osteopenia, has been demonstrated in most studies. Interestingly, trials investigating the benefits of oral vitamin D supplements (400–800 IU/day) found limited success in patients. Owing to the theoretical advantage of supplementation in conditions associated with poor nutrient absorption, larger trials involving higher doses or different forms are expected to determine the most effective treatment (Buchman 1999, Congden et al 1981, Hanly et al 1985, Hoffmann & Zeitz 2000, Jahnsen et al 2002). A study of children with cystic fibrosis demonstrated 25(OH)D levels that were consistently > 50 nmol/L with an average dose of 1405 IU/day.

Cancer

In the 1930s it was reported that US navy personnel exposed to high-level UVB showed higher rates of skin cancer but lower rates of cancer malignancies (Giovanucci 2008, Grant 2008a). WHO data from as early as 1955 have demonstrated latitudinal gradients in cancer mortality rates for breast, colon, lung, prostate, rectal and renal cancer (Grant 2008a); however, the hypothesis linking UVB, vitamin D and cancer was not formally proposed until 1980. Since this time, ongoing epidemiological evidence has demonstrated in both single and multiple country studies that there is increasing cancer incidence or mortality with increasing distance from the equator (Garland et al 1999, Grant 2008a). Both advancing age and ethnicity have also been positively correlated with these cancers and this has been similarly explained in relation to reduced UVB exposure. Further epidemiological support comes from the inverse relationship between prospective serum 25(OH)D levels and cancer risk, season of cancer diagnosis and survival time and lower rates of cancer in high fish-consuming countries such as Iceland and Japan (Giovanucci 2008, Grant 2008a). Following on from this, in 2002 Grant identified 14 cancers for which there was strong evidence to support vitamin D sensitivity, including breast, colon, ovarian, prostate and rectal forms.

More recent evidence from an interventional study of calcium (1400–1500 mg/day), alone or with vitamin D_3 (1100 IU/day) versus a placebo over 4 years supports a chemoprotective role for vitamin D (Lappe et al 2007). The study, involving 1179 women > 55 years old, was primarily designed to assess reductions in fracture incidence, but upon further analysis also demonstrated significant risk reduction (RR 0.40) for all cancer incidence in the combined calcium and vitamin D group. When the analysis was restricted to those cancers diagnosed only after the first year of treatment, the RR became 0.23. While the group receiving calcium alone also demonstrated a reduced risk, the researchers speculate that this may not be robust and conclude that vitamin D is the key variable in reduced incidence of all cancer. Given the ability of vitamin D to inhibit abnormal proliferation, facilitate apoptosis, attenuate growth signals and reduce angiogenesis around tumours, its chemoprotective potential continues to be enthusiastically investigated through both in vitro studies and RCTs (Giovanucci 2008, Grant 2008a). Risk reduction via protection against viral infections has also recently been hypothesised (Grant 2008b).

Colorectal cancer and prevention of adenomatous polyps

Evidence of vitamin D's chemoprotective effect is strongest in relation to colorectal cancer (Giovanucci 2008) and comes from several different lines of investigation (Garland et al 1991, Giovanucci 2008, Grant & Garland 2004, Holt et al 2002, Holt 2008, Theodoratou et al 2008). A 2004 review of more than 20 epidemiological studies of vitamin D and colorectal cancer concluded that the overwhelming majority of studies have demonstrated an inverse relationship between dietary intake, serum 25(OH)D and incidence (Garland et al 2004). An estimate of daily requirements needed for prevention has been formulated using the data from the studies, suggesting that an oral intake of > 1000 IU/day of vitamin D or serum 25(OH)D levels of > 33 ng/mL (82 nmol/L) could reduce the risk of colorectal cancer by as much as 50%. Most intervention studies to date, however, have focused on calcium supplementation. Interestingly, some of these show calcium's protective effect against recurrent adenomas is largely restricted to individuals with baseline serum 25(OH)D above the median (≥ 29 ng/mL). These data, together with more recent findings (Mizoue et al 2008), strongly point to a synergism between calcium and vitamin D for colorectal cancer and recurring adenoma risk reduction (Grau et al 2003, Holt 2008, Oh et al 2007, Theodoratou et al 2008). An often-cited negative finding comes from the Women's Health Initiative (WHI), in which women supplemented with 1000 mg calcium and 400 IU vitamin D per day failed to demonstrate reduced cancer rates; however, several authors have published major criticisms of the study that include the inadequate dose of vitamin D administered and the time frame (Giovanucci 2008, Grant 2008a, Holt 2008). Re-analysis of the WHI findings has also elucidated oestrogen's critical modifying effect upon both nutrients, whereby higher oestrogen levels of both menstruating and postmenopausal women taking HRT negate calcium's otherwise protective effect (Ding et al 2008). Explanations for this phenomenon include competitive binding between vitamin D and oestrogen (Ding et al 2008, Oh et al 2007).

Current evidence for a combined protective role of calcium, either dietary or supplemental, and vitamin D, particularly in men and postmenopausal women not taking HRT, is strong and further elucidation of the independent and combined effects of these nutrients will assist in the development of preventative protocols.

Prostate

Vitamin D's relationship to cancer is least clear with respect to prostate cancer, with inconsistent findings from numerous studies (Giovanucci 2008, Li et al 2007, Mucci & Spiegelman 2008). Most recently, the belief that increased calcium, dairy consumption and vitamin D levels could increase risk has dominated, with epidemiological evidence from a number of substantial studies, including the Helsinki Heart Study involving 19,000 men. This study showed that increased levels of circulating $1,25(OH)_2D_3$ and low levels of 25(OH)D are inversely associated with prostate cancer, in both incidence and aggressiveness, and are associated with an earlier age of onset (Chen & Holick 2003, Mucci & Spiegelman 2008). However, evidence of the potentially protective effects of increased serum 25(OH)D and $1,25(OH)_2D$ continue to emerge (Li et al 2007), while more comprehensive investigations of the relationship between dietary vitamin D intake and risk fail to show any effect (Huncharek et al 2008), largely due to globally poor intakes. Several explanations for these contrasting findings have been proposed, including that vitamin D status many years prior to diagnosis may be more predictive and relevant than levels just before or following diagnosis (Giovanucci 2008, Mucci & Speigelman 2008).

Experimental research with vitamin D has produced interesting results. Prostate cancer cells in vitro respond to vitamin D_3 with reduced proliferation, increased differentiation and apoptosis. More recently, reduced activity of the 1-alpha-hydroxylase enzyme in cancerous prostate cells when compared to healthy prostate tissue was discovered, resulting in a reduced ability to convert vitamin D to its active form. Therefore, prostates with cancer display partial resistance to the tumour-suppressing activity of $1,25\text{-}(OH)_2D_3$ (Ma et al 2004). Clinical trials using supplemental vitamin D at various stages of prostate cancer have yielded inconsistent results (Miller 1999).

Breast

Normal breast cells produce $1,25(OH)_2D$, which in turn may contribute to healthy mammary function, inducing differentiation, inhibiting proliferation and modulating immune responses (Perez-Lopez 2008). Vitamin D receptors in mammary tissue have also been shown to oppose oestrogen-driven proliferation of cells (Welsh et al 2003). In addition,

there is growing epidemiological evidence to suggest an inverse association between vitamin D and breast cancer (Grant 2006, Grant 2008c, Mohr et al 2008, Perez-Lopez 2008), with increasing UVB exposure reported to produce a RR of between 0.67 and 0.85 (Perez-Lopez 2008). One study that involved 179 breast cancer patients and 179 controls assessed vitamin D status of patients and polymorphisms of vitamin D, and identified an inverse relationship, possibly as high as 7-fold, between 25(OH)D levels and breast cancer risk (Lowe et al 2005). Interestingly, from a population-based case control study in Ontario, there is evidence to suggest that sun exposure between the ages of 10 and 19 years is particularly protective against subsequent breast cancer diagnoses (Perez-Lopez 2008). This implies that vitamin D status may be especially important during breast development.

A more recent investigation of the effect of UVB exposure on breast cancer incidence in 107 countries also confirmed that increased UVB exposure is independently protective, with age-standardised incidence rates substantially higher at latitudes distant from the equator (Mohr et al 2008). The same study demonstrated that the protective effect was evident at serum levels above 22 ng/mL. Another study revealed that women with serum 25(OH)D ≥ 50 ng/mL halve their risk of breast cancer compared to those below this cut-off level (Perez-Lopez 2008).

A recent large meta-analysis of dietary studies initially failed to find a relationship between vitamin D intake and breast cancer risk. Restricting studies to only those with intakes > 400 IU/day, however, revealed a trend towards risk reduction with increasing vitamin D intake (RR 0.92) (Gissel 2008).

Type 1 diabetes mellitus (T1DM)

Vitamin D deficiency has been linked to both types of diabetes mellitus, but the largest volume of evidence relates to an inverse association between prenatal and infant vitamin D levels and a child's overall risk of developing T1DM. International epidemiological data highlight a marked geographical pattern of increasing incidence with increasing latitudes, together with significantly greater rates of diagnosis in autumn and winter (Svensson et al 2008, Zipitis & Akobeng 2008). In addition to this, assessment of T1DM patients reveals significantly lower 25(OH)D than age-matched controls. Given that the beta-cell destruction of T1DM frequently begins in infancy, with diagnosis typically occurring when 80% of cells have already been destroyed, much focus has been placed on the environmental and nutritional influences in early life as potential aetiological factors.

One birth cohort study published in *Lancet* in 2001 involved the offspring of 12,055 pregnant Finnish women who gave birth in 1966. The families were assessed for vitamin D supplementation in the infant's first year of life and then the child was followed until 31 years of age to account for subsequent diagnoses of T1DM. It was shown that treatment of children with 2000 IU/day vitamin D from 1 year of age decreased the risk of developing the disease by 80% through the next 20 years; furthermore, children from the same cohort who were vitamin D-deficient at 1 year old had a four-fold increased risk of developing T1DM (Hypponen et al 2001). Similar findings have been demonstrated in animal models, with pretreatment with $1,25(OH)_2D$ being effective in mitigating or preventing the onset of T1DM (Palomer et al 2008).

A case control study conducted in Norway that involved 545 Norwegian children up to 15 years old with T1DM retrospectively assessed their cod liver oil and vitamin D use from birth to 12 months old. Children who had been given cod liver oil five times a week had a 26% lower incidence of the disease, whereas other forms of vitamin D appeared to bear no relationship (Stene & Joner 2003). Although this does not adequately assess vitamin D as a sole treatment agent and is not conclusive, it adds to the growing body of evidence implicating vitamin D in a preventative role against diabetes.

A recent meta-analysis of five studies of vitamin D supplementation in infancy, including the above two, concluded that supplementation during an infant's first year appears to be associated with a significant risk reduction for the development of T1DM later in life (OR 0.71) (Zipitis & Akobeng 2008). Current evidence points to the superiority of cod liver oil as a delivery form, but a lack of specific detail in many of the studies means that optimal dose, duration of supplementation and timing can not currently be elucidated.

Type 2 diabetes mellitus (T2DM)

Epidemiological studies suggest that vitamin D deficiency places some populations (e.g. non-Hispanic blacks) at a higher risk of insulin resistance, impaired glucose homeostasis and metabolic syndrome (Palomer et al 2008). The mechanisms for this effect remain speculative, including suppression of parathyroid hormone (PTH), reducing calcium influx and therefore limiting lipogenesis etc. Other theories relate to vitamin D's immunomodulatory actions. A range of elevated inflammatory markers have been identified to predate the onset of T2DM and many of these appear to be downregulated by vitamin D, but direct evidence of this pathogenetic path is currently lacking (Palomer et al 2008). The relationship between diabetes and vitamin D, however, is likely to be a bidirectional one, with low levels of functioning insulin impairing bioactivation of vitamin D, and poor vitamin D status impeding correct insulin release and function.

Consistent evidence of an inverse relationship between serum 25(OH)D and adiposity highlights another domain of potential overlap between hypovitaminosis D and T2DM (Alemzadeh et al 2008, Palomer et al 2008). Consequently, vitamin D deficiency is common in T2DM patients (Sugden et al 2008). One study revealed that three-quarters of obese adolescents had levels < 50 nmol/L, with a positive correlation between poor vitamin D status and glucose dysregulation (Alemzadeh et al 2008), while 49% adult T2DM patients in another study demonstrated vitamin D deficiency (Sugden et al

2008). A recent meta-analysis concurs with these findings, while also adding calcium to the equation; it calculates an OR of 0.82 for incident T2DM among individuals with low vitamin D status, calcium or dairy intake (Pittas et al 2007).

Vitamin D supplementation in patients with mild T2DM and in non-diabetic patients with vitamin D deficiency can improve insulin secretion in response to oral glucose loads, but it is ineffective in patients with established or severe T2DM (Palomer et al 2008). In one clinical trial, 1332 IU/day oral vitamin D was administered for 1 month to 10 adult women with T2DM. Corresponding changes were observed in first-phase insulin secretion (34.3% increase) and serum 25(OH)D levels. Improvements observed in second-phase insulin secretion and insulin resistance were deemed non-significant (Borissova et al 2003). A more recent pilot study employed a single high dose of D_2 (100,000 IU) to vitamin-D-deficient T2DM patients; this resulted in improved endothelial function, as evidenced by a highly significant reduction in systolic blood pressure. The proposed mechanisms for this effect are many and varied but remain hypothetical at this time (Sugden et al 2008). IV administration of vitamin D to patients with gestational diabetes produces a transient reduction in both fasting glucose and insulin, suggesting improved insulin sensitivity rather than secretion (Palomer et al 2008).

It is important to note that single high-dose vitamin D actually increases blood glucose levels in patients with diabetes (Palomer et al 2008).

Hypoparathyroidism

Vitamin D in combination with calcium has established benefits in the treatment of hypoparathyroidism, by promoting homeostasis of calcium, phosphorus, 25 (OH)D and PTH levels (Mimouni et al 1986).

Secondary hyperparathyroidism

In a controlled study of 100 postmenopausal women with confirmed vitamin D deficiency (< 18 nmol), supplementation with combination calcium and low-dose vitamin D showed more significant reductions in PTH levels over the 90-day trial period than supplementation with calcium alone (Deroisy et al 2002).

Hypophosphataemia

A combination of high-dose vitamin D and phosphorus results in improved phosphorus and calcium balance in these patients (Lyles et al 1982).

Osteoporosis and fracture prevention

Both serum 25(OH)D and $1,25(OH)_2D$ levels are low in osteoporotic patients (Cranney et al 2008, Hunter et al 2000, Wilson et al 1991); however, conclusions regarding improvement of bone health with vitamin D supplementation alone have been mixed and largely hampered by methodological issues (e.g. accurate vitamin D assessment, accounting and discriminating between different vitamin D sources, extricating effects of vitamin D from those of calcium) (Cranney et al 2008). A 2008 systematic review that included 17 RCTs of either D_2 or D_3 supplementation (300–2000 IU/day) in postmenopausal women or older men has found consistent evidence of a protective effect of D_3 at doses of ≥ 700 IU/day in combination with calcium (500–1200 mg/day) (Cranney et al 2008). Notably, however, vitamin D at these doses provided no additional benefits in black populations. A recent meta-analysis of 29 RCTs conducted in 63,897 individuals ≥ 50 years over an average of 3.5 years also concluded that calcium alone (≥ 1200 mg/day) or in combination with vitamin D (≥ 800 IU/day) reduced the risk of fracture by 12–24%, and reduced bone loss by 0.54% at the hip and 1.19% at the spine (Tang et al 2007). The greatest improvements were noted specifically in the elderly, institutionalised, underweight and calcium-deficient. In addition, a recent Australian trial that investigated the administration to 120 women aged 70–80 years of 1200 mg/day of calcium alone or in combination with 1000 IU vitamin D over 5 years yielded beneficial effects on bone mineral density (BMD) and bone turnover markers for both treatment groups, with evidence of more sustained improvements in those also taking vitamin D (Zhu et al 2008). Another recent study comparing the combined effects of calcium (500 mg/day) with either oral vitamin D_2 (700 IU/day) or calcitriol over 3 years demonstrated a protective effect of vitamin D_2 on the spine but not on the hip (Zofkova & Hill 2007).

Serum 25(OH)D levels in postmenopausal women are inversely associated with fracture risk, independent of number of falls, physical functionality, frailty and other associated risks (Cauley et al 2008). These data reveal that individuals with baseline serum levels < 47.5 nmol/L have an increased risk of hip fracture rate over the next 7 years of 1.71 compared to those with values > 70.7 nmol/L. Other studies of similar design concur with these results, while producing different cut-off values. Studies investigating vitamin D supplementation for fracture prevention in osteoporosis have produced some positive results. In the context of adequate or supplemented calcium, a 60% reduction in the incidence of peripheral fractures was observed by Cosman (700–800 IU/day), with a 40% reduction in hip fracture incidence specifically (Cosman 2005). A recent systematic review of 15 RCTs involving mostly D_3 supplementation (300–800 IU/day) found a non-significant reduction in fractures; however, methodological limitations, including the relatively low dose, could be a confounding issue (Cranney et al 2008).

One study has investigated the BMD effects of co-supplementing silicon with calcium and vitamin D. In a recent RCT of 136 predominantly postmenopausal osteopenic women, 1000 mg calcium, 20 mcg vitamin D and either 3 mg, 6 mg or 12 mg silicon in the form of orthosilicic acid was administered daily for 12 months to the treatment group. These subjects demonstrated significantly greater type I collagen, indicative of increased bone synthesis, compared to those receiving the placebo (Spector et al 2008). There was also a trend of decreasing resorption with increasing silicon dose.

The mechanisms behind vitamin D's bone actions are not limited to the suppression of PTH and improved calcium balance alone; evidence also exists of direct inhibition of bone resorption and reduced inflammatory markers. There is also speculation regarding vitamin D's potential positive effects on lean body mass, which would then convey an anabolic effect via increased mechanical load (Cauley et al 2008, Zofkova & Hill 2007).

Reducing falls in the elderly

Poor vitamin D status (e.g. low serum 25(OH)D, compromised VDR numbers or binding affinity, colder seasons) is independently associated with an increased risk of falling in the elderly, particularly in those aged 65–75 years (Prince et al 2008, Richy et al 2008, Snijder et al 2006) and in some studies with poorer physical performance generally (Brunner et al 2008). A 2004 review of double-blind RCTs of vitamin D in elderly populations concluded that vitamin D supplementation reduced the risk of falling by more than 20%. The results were significant only in women and appeared to be independent of calcium administration, type of vitamin D and duration of therapy (Bischoff-Ferrari et al 2006). More recent research has suggested an even greater effect, but the degree of risk reduction varies between studies. According to a double-blind randomised trial involving 64 institutionalised elderly women (age range: 65–97 years; mean 25(OH)D levels: 16.4 ng/mL), treatment with 1200 mg/day calcium plus 800 IU/day D_3 over 3 months reduced the rate of falls by 60% compared with calcium supplementation alone (Bischoff-Ferrari et al 2006). An Australian study of community-based women aged 70–90 years with baseline serum 25(OH)D < 24 ng/mL found that D_2 (1000 IU/day) in combination with 1000 mg calcium citrate over 1 year reduced falls by 19% (Prince et al 2008). An interesting finding was the marked seasonal variation in efficacy, with vitamin D's protective effect evident in winter/spring (months exhibiting increased risk of falls generally) but not in summer/autumn. This has been attributed to the decline in serum 25(OH)D during these months and has also been postulated as an explanation for the lack of effect seen in some larger long-term studies. The researchers also concluded that a serum level of < 24 ng/mL is predictive of individuals who may benefit from vitamin D supplementation in this context.

In 2007 a pilot study of an osteopenic/porotic elderly female population ($\geq$ 65 years) investigated the possible additional clinical benefits of 3 months' exercise training and increased protein intake on top of year-long calcium and vitamin D supplementation (500–1000 mg/day and 400–800 IU/day, respectively) (Swanenburg et al 2007). Although the number of falls reduced dramatically in both groups, the group undertaking exercise training demonstrated greater and more sustained risk reduction (e.g. 100% at 6 months versus 40%). This multipronged approach appears promising and warrants further investigation. A recent systematic review funded by the US Office of Dietary Supplements of the National Institute of Health and the Agency for Healthcare Research and Quality included 14 RCTs of vitamin D for fall prevention and concluded that there was consistent evidence of benefit (OR 0.89) (Cranney et al 2008).

As a result of the accumulating evidence, routine vitamin D administration has been recommended for those institutionalised or housebound elderly who are already at risk of deficiency (Sambrook & Eisman 2002). The findings of an Australian study, however, suggest there are a significant number of community-dwelling elderly with sufficiently low vitamin D status who might also benefit from routine vitamin D (Prince et al 2008). One additional consideration is the best delivery form, with a recent comparative meta-analysis demonstrating superior results from vitamin D analogues, e.g. alfacalcidol and calcitriol, when compared to oral vitamin D (Richy et al 2008). These analogues, which override renal regulation of vitamin D bioactivation, may be particularly indicated in individuals who take high-dose glucocorticoids, exhibit impaired renal function or chronic inflammation, or who have T1DM.

Anticonvulsant-induced osteomalacia

Preliminary evidence has shown vitamin D to be an effective treatment for this condition; however, much emphasis has been placed on establishing the most superior form of D, D_2 or D_3, as they exhibit important metabolic differences in these patients (Hartwell et al 1989, Tjellesen et al 1985, 1986). Results of the RCTs to date suggest that D_2 may be the most effective form in the restoration of bone mineral content in patients on anticonvulsant treatment (Tjellesen et al 1985).

Hepatic and renal osteodystrophy

Both chronic liver disease and those conditions exhibiting end-stage renal disease result in compromised hydroxylation of vitamin D to produce its active metabolite. It has been reported that 50% of patients with chronic liver disease, especially those with primary or secondary biliary cirrhosis, present with associated osteodystrophy. This frequently leads to a vitamin D deficiency and manifests most commonly as metabolic bone disorders, hypocalcaemia and secondary hyperparathyroidism (Wills & Savory 1984). The resultant hypovitaminosis D can result in bone loss, cardiovascular disease, immune suppression and increased mortality in patients with end-stage kidney failure (Andress 2006). Consequently, correction of this deficiency has been one of many first-line treatments in these situations.

Although vitamin D_2 supplementation in combination with calcium, phosphorus and magnesium (where indicated) has shown some success in those patients with hepatic osteodystrophy (Compston et al 1979, Long & Wills 1978), recent trials and emerging research implicate other factors in the aetiology of these sequelae (Klein et al 2002, Suzuki et al 1998). As such, therapy with D_2 may need to be reviewed.

The treatment of renal osteodystrophy is reliant upon only the active forms or analogues of vitamin D, and natural supplementation is ineffective

because of the inability to convert these precursors into 1,25-alpha-$(OH)_2$D (Kim & Sprague 2002).

Localised and systemic scleroderma

Although patients suffering from scleroderma do not show compromised D synthesis (Matsuoka et al 1991), vitamin D_3 has been investigated as a therapeutic agent to moderate the excessive proliferation and collagen production typically seen in this condition. An in vitro study assessing the action of vitamin D_3 on the behaviour of affected fibroblasts has confirmed a non-selective antiproliferative action (Boelsma et al 1995).

To date, clinical studies have produced mixed results. Clinical trials focusing on generalised scleroderma have involved small numbers and produced promising results, such as increased joint mobility, reduced induration and increased extensibility of the skin, with benefits lasting at least 1 year after discontinuation of treatment (Caca-Biljanovska et al 1999, Hulshof et al 1994). However, the largest RCT involving 27 patients (the majority of whom suffered a localised condition) found that treatment over 9 months with a similar dose of D_3 failed to produce any significant changes in any of the assessment criteria (Hulshof et al 2000). These results suggest that different therapies may be required for the two conditions; however, larger controlled studies are needed to confirm those positive results from the preliminary open trials.

Prevention and treatment of infections

The potential immune-enhancing effect of vitamin D was first described indirectly in 1849, when cod liver oil was attributed with being one of the most efficacious agents in the treatment of pulmonary tuberculosis (PTB) (Maalouf 2008). Remarkably, in spite of mounting evidence regarding the vast and potent immunomodulatory effects of vitamin D, the evidence supporting its use in the prevention and treatment of infections has not progressed substantially and the small number of in vivo studies conducted in this area possess marked methodological weaknesses. The most robust evidence to date comes from a small study of 67 PTB patients, who received 10,000 IU/day in addition to standard antimycobacterial treatment and showed higher rates of sputum conversion and radiological improvement as a result. Several post-hoc analyses of vitamin D supplementation studies using other primary outcomes (e.g. fracture) have revealed trends of decreasing infections, colds and flu for those individuals taking a minimum of 800 IU/day (Grant 2008b, Maalouf 2008).

Depression

Patients with primary hyperparathyroidism, which secondarily impedes the bioactivation of vitamin D and raises serum calcium, frequently present with depressive disorders that normalise following successful PTH lowering (Hoogendijk et al 2008). Rodents deficient in VDR demonstrate mood abnormalities that include increased anxiety (Hoogendijk et al 2008, Jorde et al 2006, Obradovic et al 2006) and the presence of both VDR and 1-alpha-hydroxylase activity in specific brain regions (e.g. hypothalamus) implies a potential role for vitamin D as a neuroactive hormone (Berk et al 2007, Obradovic et al 2006, Vieth et al 2004). There is also increasing evidence of vitamin D's modulation of several neurotransmitters, such as acetylcholine, catecholamines and serotonin (Jorde et al 2006, Obradovic et al 2006). Yet in spite of such strong theoretical underpinning, concerted research into the links between vitamin D and mood have only recently begun in earnest.

Recent epidemiological data reveal a strong independent inverse relationship between serum 25(OH)D and both depression scores and cognitive impairment in elderly subjects (Hoogendijk et al 2008, Johnson et al 2008, Wilkins et al 2006), premenstrual syndrome, seasonal affective disorder (SAD), non-specific mood disorder and major depressive disorder in women (Murphy & Wagner 2008), depression and anxiety in fibromyalgia patients (Armstrong et al 2007), depression rating scores on the Beck Depression Inventory in overweight and obese patients (Jorde et al 2008), and significantly lower vitamin D levels in patients with uni- and bipolar depression compared with matched controls (Berk et al 2007).

Initial interventional studies of vitamin D supplementation produced mixed findings in depression, SAD and general wellbeing; however, notably low doses were used (400 IU/day over short durations and in small samples), which may partly explain this lack of effect in some studies (Berk et al 2007, Hoogendijk et al 2008, Lansdowne & Provost 1998). More recent study designs have attempted to account for such shortcomings and have produced more consistent results (Jorde et al 2008, Vieth et al 2004). In two studies thyroid outpatients with low vitamin D status during summer received either 600 IU or 4000 IU/day over the following 6 months (a placebo treatment was deemed unethical, given confirmation of hypovitaminosis D of all subjects at baseline). When vitamin D status and wellbeing questionnaires were repeated the following winter, improvements in mood and self-reported health were noted, particularly in those patients taking 4000 IU/day and those with the lowest serum concentrations at baseline. Another study of 441 overweight and obese individuals, only some of whom had vitamin D deficiency, found that supplementation with either 40,000 IU/week or 20,000 IU per week in combination with 500 mg/day calcium over 1 year produced significant reductions in depression rating scores (Jorde et al 2008). The greatest effects were evident in those with higher depression scores at baseline and were independent of both BMI and initial serum 25(OH)D values. Another recent study of elderly women supplemented with 800 IU/day and 1000 mg/day calcium, however, failed to produce improvements on mental health scores (Dumville et al 2006).

Vieth et al (2004) comment that previous studies have suggested gender-specific mood effects of vitamin D, with women being more susceptible to seasonally dependent mood lability and more responsive to supplementation. They also identify

many potential modulating influences upon vitamin D's mood effects which future researchers must take into consideration in addition to baseline 25(OH)D: season, dose, duration, age and sex. More well-designed research is needed in this area to clarify the real therapeutic potential of vitamin D in depressed mood.

OTHER USES

Multiple sclerosis (MS)

There is reasonably strong ecologic and case–control evidence that improved vitamin D status reduces the risk of multiple sclerosis (Grant 2006, Kampman & Brustad 2008, Niino et al 2008, Smolders et al 2008). A variety of observational studies illustrate a relationship between MS incidence and geographical location, with very low prevalence in the equatorial regions and increasing risk with increasing latitude in both hemispheres. Other demonstrated associations with MS incidence include the level of outdoor activity in adolescents and risk of onset later in life, while there is evidence of lower 25(OH)D levels in newly diagnosed patients when compared to controls and in relapsing patients compared to those in remission (Kampman & Brustad 2008, Niino et al 2008, Smolders et al 2008). Evidence is more mixed regarding VDR polymorphisms, month of birth and season of diagnosis. In spite of these findings, strong evidence linking vitamin D to modulation of MS is currently lacking. A very limited number of interventional studies using vitamin D also leave us without a firm conclusion. Some studies, including the Nurses Health Study, point towards a protective effect in the years following regular supplement use, but the effects of vitamin D are difficult to extricate from other supplemented nutrients. In an open and uncontrolled study of 39 MS patients treated with 1000 IU/day for 6 months, changes in inflammatory markers were observed but clinical benefits were not investigated. The most promising study to date was conducted in 12 patients administered 1000 IU/day over 28 weeks, which reduced the number of gadolinium enhancing lesions on the magnetic resonance imaging (MRI) of one subject (Smolders et al 2008).

Lupus (SLE)

There is growing evidence suggesting an aetiological role for vitamin D in SLE, as in MS and other autoimmune diseases. In addition to epidemiological studies showing low 25(OH)D in SLE patients compared to healthy controls, and inverse correlations between vitamin D status and disease severity, individuals with this condition are identified as being at high risk of vitamin D deficiency because of a range of factors (Cutolo & Otsa 2008, Kamen & Aranow 2008). These factors include increased photosensitivity, renal involvement impeding bioactivation and evidence of anti-D antibodies in select patient subsets. Data from animal and in vitro studies also point to vitamin D as an effective treatment, in particular reversing the characteristic immune abnormalities, while experimentally induced deficiencies exacerbate clinical features. Interventional studies in SLE patients are now required to confirm this indication.

Psoriasis

As a regulator of cellular growth and differentiation in various tissues, vitamin D has been investigated in psoriasis. The active form of vitamin D and its analogues have been found to suppress growth and stimulate the terminal differentiation of keratinocytes.

Vaginal atrophy

Animal studies have revealed the presence of VDR in the cells lining the vagina (Yildirim et al 2004a). Given the established role of vitamin D in regulating growth and differentiation of tissues, especially those lining stratified squamous epithelium, a possible role for vitamin D in the prevention and treatment of vaginal atrophy associated with menopause is being considered (Yildirim et al 2004b). A number of studies involving co-administration with

Clinical note — A link between vitamin D and schizophrenia?

The epidemiological correlation between babies born in winter and spring and an increased prevalence of schizophrenia has been a long-established phenomenon and presented many riddles for researchers (Kendell & Adams 2002). The association has also been observed in cities where air pollution reduces UV irradiation, and, more recently, a 7–10-fold increased risk has been identified in second-generation dark-skinned migrants. These observations have led to the emergence of a neurodevelopmental theory of schizophrenia, which suggests that low prenatal vitamin D interferes with brain development by interacting with D-responsive/susceptible genes to create the currently recognised polygenic effects of schizophrenia (Mackay-Sim et al 2004).

A significant progression of this theory was made at the Queensland Centre for Schizophrenic Research led by Professor John McGrath. The centre's work has taken the level of evidence beyond the early epidemiological findings, with research being conducted to assess the impact of vitamin D deficiency on animal brains and in vitro cultures. Research has also been conducted to measure third-trimester serum 25(OH)D levels in schizophrenic and schizoaffective mothers, while investigating the impact of vitamin D supplementation prior to 1 year of age in the infants and the subsequent risk reduction for the disease in later life (McGrath et al 2003, 2004a, 2004b). The preliminary evidence to date shows weak support for this hypothesis, with a consistent positive relationship appearing for males, and evidence pointing towards a stronger relationship in dark-skinned populations compared to fairer skinned populations.

calcium have produced some positive results; however, a recent trial of calcium and D_3 (500 mg/day and 400 IU/day, respectively) used as a replacement for transdermal oestrogen replacement therapy in menopausal women over 1 year revealed an objective worsening of vaginal atrophy (Checa et al 2005). Dose, however, may be an issue.

DOSAGE RANGE

Acceptable daily intake (ADI)

The NHMRC vitamin guidelines released in 2006 make the following recommendations for ADI:

- Children and adults < 50 years: 200 IU/day.
- Adults 51–70 years: 400 IU/day.
- Adults over 70 years: 600 IU/day.

The ADI is based on the amount of vitamin D required to maintain serum 25(OH)D at a level of at least 27.5 nmol/L with minimal sun exposure. The level has been raised in the 51–70 year age group to account for the reduced capacity of the skin to produce vitamin D with ageing. The higher level recommended in the over 70 years group was made because this group tends to have less exposure to sunlight.

According to clinical studies

(D_3 supplemental form unless otherwise indicated.)

- Uncomplicated rickets: 1600 IU/day for the first month, gradually reducing the dose to 400 IU.
- Osteomalacia: 36,000 IU/day with calcium supplementation.
- Rickets and osteomalacia due to defective metabolism: 50,000–300,000 IU/day.
- Pregnancy supplementation: two large doses of 600,000 IU in the seventh and eighth months (Marya et al 1981).
- Reduction in fractures associated with osteoporosis: prevention of fractures has resulted from as little as 200 IU/day in combination with calcium, but the most effective dose is ≥ 800 IU/day in combination with ≥ 1200 mg/day calcium.
- Reduction in falls: 1000 IU/day in combination with 1000 mg/day calcium.
- Hyperparathyroidism: 2.5–6.25 mg/day.
- Hepatic osteodystrophy: 4000 IU/day.
- Anticonvulsant osteomalacia: 4000 IU D_2/day for 105 days, followed by 1000 IU/day.
- Systemic scleroderma: 0.75–1.25 μg D_3 for 6 months.

TOXICITY

Toxic ingestion of prescribed forms of vitamin D or excessive dietary consumption of either D_2 or D_3 has been reported in the vicinity of 50,000–100,000 IU/day or 10,000 IU/day taken routinely for several months. Obtaining such enormous amounts from unfortified foods is improbable. Traditionally the toxicity picture of vitamin D has been attributed to a secondary hypercalcaemia, which manifests as anorexia, nausea, vomiting, polyuria, muscle pain, unusual tiredness, dry mouth, persistent headache and secondary polydipsia. Over extended periods of time, this state of hypervitaminosis can result in metastatic calcification of soft tissues including kidney, blood vessels, heart and lungs. Symptoms and signs at this later stage include cloudy urine, pruritis, drowsiness, weight loss, sensitivity to light, hypertension, arrhythmia, fever and abdominal pain. Toxic levels cannot be obtained from excessive sun exposure (FAO/WHO 2002, Gropper et al 2009). More recent research into vitamin D pharmacokinetics, however, points towards 25(OH)D's ability at high doses to displace $1,25(OH)_2D$ from VDR, therefore increasing free concentrations of the active form and subsequent gene transcription (Jones 2008).

ADVERSE REACTIONS

High doses of supplements may induce the following:

- arterial calcification
- arrhythmia
- gastrointestinal distress, including nausea, vomiting and constipation
- hypercalcaemia
- nephrotoxicity, manifesting as polyuria, polydipsia and nocturia.

SIGNIFICANT INTERACTIONS

Only those interactions relevant to the oral supplemental forms of vitamin D will be reviewed.

A number of pharmacokinetic and pharmacodynamic interactions are possible with vitamin D and a range of medicines and minerals.

Antituberculosis drugs

Drugs such as rifampicin and isoniazid have been reported to induce catabolism of vitamin D and in some cases manifest as reduced levels of metabolites. This may represent a concern in those patients already at risk of poor vitamin D status (Harkness & Bratman 2003).

Calcium-channel blockers

Vitamin D supplementation may reduce effectiveness of these drugs. Use with caution unless under medical supervision (Harkness & Bratman 2003).

Glucocorticoids

In high doses, these drugs directly inhibit vitamin-D-mediated calcium uptake in the gastrointestinal tract and through unknown mechanisms may deplete levels of active vitamin D (Wilson et al 1991). During long-term therapy with either oral or inhaled corticosteroids, calcium and vitamin D supplementation should be considered.

Ketoconazole

This drug reduces the conversion of vitamin D to its active forms. Increased vitamin D intake may be required with long-term drug use.

Lipid-lowering drugs

Drugs such as cholestyramine and colestipol may compromise the absorption of all fat-soluble vitamins. To avoid the interaction, administer the supplement at least 1 hour prior to or 4–6 hours after ingestion of the drug (Harkness & Bratman 2003). Conversely, long-term use of statins is

associated with increased 25(OH)D levels via an unknown mechanism (Aloia et al 2007).

Magnesium
Either an excess or inadequate level of magnesium can impact on vitamin D status. The final hydroxylation step to $1,25(OH)_2D_3$ is dependent upon magnesium and a deficiency would compromise this. However, high levels of magnesium, mimicking calcium, can suppress PTH secretion, also suppressing the activation phase (Groff & Gropper 2005). Therefore magnesium levels within the normal range will enhance activation of vitamin D to its active form.

Mineral oil
Mineral oil impairs absorption of all fat-soluble nutrients and may therefore deplete oral intake of vitamin D sources. Separate doses by at least 2 hours.

Oestrogens
Vitamin D works synergistically with oestrogens to prevent bone loss. Interaction is beneficial.

Orlistat
Although orlistat has been shown to reduce the absorption of some fat-soluble nutrients, its effect on vitamin D specifically remains unclear. Concurrent supplementation of a multivitamin with D is advised. Separate doses by a minimum of 4 hours either side of ingestion of orlistat (Harkness & Bratman 2003).

Phenytoin and valproate
The anticonvulsants induce catabolism of vitamin D through liver induction and prolonged use is associated with increased risk of developing rickets and osteomalacia.

CONTRAINDICATIONS AND PRECAUTIONS
- Hypersensitivity to vitamin D.
- Hypercalcaemia.
- Not to be taken in sarcoidosis or hyperparathyroidism without medical supervision.
- Possible interference with the action of calcium-channel blockers.
- High doses require medical supervision in patients with arteriosclerosis and heart disease.
- High doses capable of inducing hypercalcaemia may precipitate arrhythmias in patients taking digitalis.

PREGNANCY USE
Vitamin D supplements as either D_2 or D_3 are exempt from pregnancy classification by the TGA, which reflects their safety in pregnancy and lactation (Australian Drug Evaluation Committee 1999).

PATIENTS' FAQs
What will this vitamin do for me?
Vitamin D is essential for health and wellbeing. It plays a critical role in regulating calcium and phosphorus levels in the body, and is important for healthy bones and preventing abnormal cell changes, which may increase the risk of some cancers.

PRACTICE POINTS/PATIENT COUNSELLING
- Vitamin D has a critical role in bone growth and development, but also has diverse roles throughout the body, including inhibiting abnormal proliferation of cells.
- Most vitamin D is endogenously produced through sun exposure and an activation process that involves both the liver and the kidneys; food sources represent a secondary and often unreliable source. Those groups in the community who have restricted sun exposure are at the greatest risk of a deficiency, including the elderly, newborns, institutionalised, adolescents and young children with marginal calcium intake during rapid growth periods, and those with dark skins.
- In the prevention of falls and prevention or treatment of osteoporosis, vitamin D supplements are most commonly given in combination with other nutrients, such as calcium.
- Other uses for vitamin D include: supplementation during pregnancy to increase fetal levels; correction of deficiencies that may result from medications or malabsorptive diseases such as coeliac disease, Crohn's disease and cystic fibrosis; as a protective agent against breast, prostate and colorectal cancer; and for a variety of metabolic bone disorders.

When will it start to work?
This will depend on the condition being treated. In uncomplicated rickets, serum levels should begin to rise in 1–2 days, and after 3 weeks signs of calcium and phosphorus mineralisation appear on X-ray.
Are there any safety issues?
Vitamin D is considered a safe supplement when used in the recommended doses; however, it may interact with some medicines.

Vitamin E

HISTORICAL NOTE Vitamin E was first discovered in 1922 at the University of California in Berkeley when it was observed that rats required the nutrient in order to maintain their fertility. In this way, vitamin E became known as the antisterility vitamin, which is reflected in its name, as *tokos* and *pherein* are the Greek words for 'offspring' and 'to bear'. Although considered an essential nutrient, it was not until the mid-1960s that deficiency states in humans were first identified. More specifically, deficiency was detected in children with fat malabsorption syndromes (Shils 1999, Wahlqvist 2002).

BACKGROUND AND RELEVANT PHARMACOKINETICS

Alpha-tocopherol is absorbed from the intestinal lumen and is dependent upon adequate fat digestion. After micellisation, it enters the lymphatic circulation and then the systemic circulation where it is transported in chylomicrons. Breakdown of chylomicrons in the blood releases some vitamin E, which is then taken up by circulating lipoproteins such as LDL and HDL. The remaining vitamin E is transported via chylomicron remnants to the liver. Here, the RRR alpha-tocopherol form is preferentially secreted back into the circulation in VLDL. It is suspected that hepatic alpha-tocopherol transfer protein is responsible for discriminating between the different types of tocopherols at this point (with the natural form preferentially taken up). Vitamin E is ultimately delivered to tissues when chylomicrons and VLDL are broken down by lipoprotein lipase. Vitamin E transported by LDL is also taken up by tissues via the LDL receptor. The bulk of vitamin E is stored in adipose tissue, although some storage also occurs in the heart, muscles, testes, uterus, adrenal and pituitary glands, and blood. Vitamin E metabolites are mainly excreted in the faeces, although some is also excreted by the kidneys and the skin (Shils 1999).

CHEMICAL COMPONENTS

To date, eight different naturally occurring compounds have been identified and named as alpha-, beta-, gamma- and delta-tocopherol and alpha-, beta-, gamma- and delta-tocotrienol. Acetate and succinate derivatives of natural and synthetic forms of vitamin E also have vitamin E-like activity, although the strength of activity varies between the different compounds and is less than the naturally occurring RRR stereoisomer D-alpha-tocopherol. The human diet generally provides a mixture of compounds with vitamin E activity.

Relative strengths of the various forms of vitamin E

The relative strength of the different forms of vitamin E can be expressed as either alpha-tocopherol equivalents (alpha-TE) or international units (IU). One alpha-TE represents the activity of 1 mg RRR-alpha-tocopherol (D-alpha-tocopherol), and the alpha-TE of natural forms of vitamin E can be calculated using simple mathematics. The number of milligrams of beta-tocopherol should be multiplied by 0.5, gamma-tocopherol by 0.1 and alpha-tocotrienol by 0.3, whereas any of the synthetic all-*rac*-alpha-tocopherols (DL-alpha-tocopherol) should be multiplied by 0.74 (FAO/WHO 2002).

More commonly, activity is described in terms of International Units (IU), where 1 mg of synthetic all-*rac*-alpha-tocopherol (DL-alpha-tocopherol) acetate is equivalent to 1 IU of vitamin E. Relative to this, 1 mg of DL-alpha-tocopherol is equal to 1.1 IU, 1 mg of D-alpha-tocopheryl acid succinate is equal to 1.21 IU and 1 mg of D-alpha-tocopheryl acetate is equal to 1.36 IU. The natural form of D-alpha-tocopherol has the highest biopotency, which is equal to at least 1.49 IU (Meydani & Hayes 2003).

FOOD SOURCES

Vitamin E is found in various forms in both animal and plant foods. The richest food sources of vitamin E are cold-pressed vegetable oils, particularly wheatgerm oil, and nuts and seeds. Other sources include spinach, kale, sweet potatoes, yams, egg yolk, liver, soya beans, asparagus and dairy products such as butter and milk. Frying, processing, bleaching, milling and freezing foods will remove some of

the vitamin E content. Overall, up to 55% can be lost through cooking (Wahlqvist 2002).

DEFICIENCY SIGNS AND SYMPTOMS

Owing to the widespread availability of vitamin E in the food chain, it is generally accepted that primary vitamin E deficiency does not occur. However, deficiency has been reported in low-birth-weight infants given infant formula or cow's milk with low vitamin E levels, and in some intestinal malabsorption syndromes such as cystic fibrosis. Genetic abnormalities in alpha-tocopherol transport protein also result in vitamin E deficiency (Shils 1999).

Ultimately, it is tissue uptake, local oxidative stress levels and polyunsaturated fat content that influence whether symptoms of deficiency develop.

Symptoms of deficiency tend to be vague and difficult to diagnose because of the nutrient's widespread actions, but the following signs and symptoms have been reported in humans (FAO/WHO 2002, Meydani & Hayes 2003):

- haemolytic anaemia
- immunological abnormalities
- neurological disturbances (e.g. peripheral neuropathies)
- platelet dysfunction
- leakage of muscle enzymes such as creatine kinase and pyruvate kinase into plasma
- increased levels of lipid peroxidation products in plasma.

MAIN ACTIONS

Vitamin E is an electron donor (reducing agent or antioxidant), and many of its biochemical and molecular functions can be accounted for by this function. It is involved in many biochemical processes in the body, but its most important biological function is that of an antioxidant and working within the antioxidant network.

Antioxidant

Vitamin E is considered to be the most important and potent lipid-soluble antioxidant. It prevents free-radical damage to the polyunsaturated fatty acids (PUFAs) within the phospholipid layer of each cell membrane and oxidation of LDL. It has been estimated that for every 1000–2000 molecules of phospholipid, one molecule of vitamin E is present for antioxidant defence (Sen & Packer 2000).

This is achieved by reacting with free-radical molecules and forming a tocopheroxyl radical, which then leaves the cell membrane. Upon entering the aqueous environment outside the membrane, it reacts with vitamin C (or other hydrogen donors such as glutathione) to become reduced and, therefore, regenerated (Vatassery 1987). In this way, vitamin E activity is influenced by what has been called the 'antioxidant network', which restores vitamin E to its unoxidised state, ready to act as an antioxidant many times over (see Clinical note for more information).

Taking a larger perspective, the collective antioxidant action at each cell membrane protects the body's tissues and organs from undue oxidative stress. Prolonged and/or excessive exposure to free radicals has been implicated in many conditions, such as cardiovascular disease, cancer initiation and promotion, degenerative diseases, and ageing in general (FAO/WHO 2002).

Regulates immunocompetence

Vitamin E increases humoral antibody production, resistance to bacterial infections, cell-mediated immunity, the T-lymphocyte response, TNF production and NK cell activity, thereby playing a role in immunocompetence. It also decreases PGE_2 production and therefore reduces its immunosuppressive effects and decreases levels of lipid peroxides

Clinical note — Free radicals, antioxidant recycling and the antioxidant network

Oxygen-containing free radicals (such as the hydroxyl radical, superoxide anion radical, hydrogen peroxide, oxygen singlet and nitric oxide radical) are highly reactive species, capable of damaging biologically important molecules such as DNA, proteins, carbohydrates and lipids. Antioxidants can break the destructive cascade of reactions initiated by free radicals by converting them into harmless derivatives.

The term 'oxidative stress' refers to an imbalance of pro-oxidants over antioxidants. The term 'antioxidant capacity' is a measure of the sum of available endogenous and exogenous defence mechanisms that work synergistically to restore and maintain the oxidative balance. During the process of maintaining oxidative balance, antioxidants such as vitamin E become oxidised themselves. Other antioxidants, such as ubiquinone, ascorbate and glutathione, are then involved in recycling vitamin E back to its unoxidised state, allowing it to continue neutralising free-radical molecules (Sen & Packer 2000). When these other antioxidants become oxidised in turn, they are also regenerated to their antioxidant forms by yet others, such as alpha-lipoic acid and cysteine. In this way, the recycling of various antioxidants occurs in an orchestrated manner. The interactions between antioxidant substances have been described as the 'antioxidant network', which comprises four parts that work together to provide a continuous defence against free-radical damage (De Vita et al 2006). These are:

- enzymes that destroy or detoxify common oxidants (e.g. catalase, glutathione peroxidase, which needs selenium)
- antioxidant vitamins, notably vitamins E and C, and coenzyme Q10, which are continuously recycled, as discussed earlier
- dietary antioxidants or phytochemicals (e.g. carotenoids, polyphenols and allyl sulfides).
- proteins that sequester iron and copper so that free forms do not exist in the body.

The antioxidant network provides a basis for recommending combinations of foods and antioxidant nutrients to provide maximal benefits, rather than single entities in high doses.

that can also adversely affect immune function (Meydani 1995).

OTHER ACTIONS

- Regulates vascular smooth-muscle-cell proliferation.
- Inhibits smooth-muscle-cell proliferation by inhibiting protein kinase C activity.
- Inhibits phospholipase A2 activity, suppressing arachidonic acid metabolism.
- Antiplatelet activity has been demonstrated in vitro, but in vivo tests have been inconsistent for D-alpha-tocopherol.
- Modulates vascular function by regulating the enzymatic activities of endothelial nitric oxide synthase (eNOS) and NAD(P)H oxidase (Ulker et al 2003).
- Analgesic activity: most likely mediated via inhibitory effects on COX-2 and 5-lipooxygenase.
- Promotes wound healing.
- Exerts neuroprotective effects.
- Gene regulation. Vitamin E modulates genes involved in cholesterol homeostasis, atherosclerosis, inflammatory pathways and cellular trafficking, including of synaptic vesicular transport and the synthesis pathways of neurotransmitters (Munteanu et al 2004, Brigelius-Flohe 2009).
  - More specifically, vitamin E regulates genes encoding proteins involved in apoptosis (CD95L, Bcl2-L1), cell-cycle regulation (p27, cyclin D1, cyclin E), cell adhesion (E-selectin, L-selectin, ICAM-1, VCAM-1, integrins), cell growth (CTGF), extracellular matrix formation/degradation (collagen alpha-1(1), glycoprotein IIb, MMP-1, MMP-19), inflammation (IL-1-beta, IL-2, IL-4, TGF-beta), lipoprotein receptors (CD36, SR-BI, SR-AI/II, LDL receptor), transcriptional control (PPAR-gamma), metabolism (CYP3A4, HMG-CoA reductase, gamma-glutamylcysteine synthetase), and other processes (leptin, a beta-secretase in neurons, tropomyosin), activation of the cellular retinoic acid-binding protein II (CRABP-II) (Brigelius-Flohe 2009).

CLINICAL USE

Although vitamin E supplementation is used to correct or prevent deficiency states, most uses are based on the concept of high-dose supplements acting as therapeutic agents to either prevent or treat various health conditions.

Deficiency: prevention and treatment

Traditionally, vitamin E supplementation has been used to treat deficiency or prevent deficiency in conditions such as genetic abnormalities with alpha-tocopherol transfer protein, apolipoprotein B, or microsomal triglyceride transfer protein (Shils 1999); and to treat fat malabsorption syndromes (e.g. chronic cholestasis, cystic fibrosis, short bowel syndromes such as Crohn's disease, chronic steatorrhea, coeliac disease, chronic pancreatitis and TPN).

Cardiovascular disease

Oxidative stress has been shown to play an integral role in the formation, progression and rupture of the atherosclerotic plaque via modification of proteins and DNA, alteration in gene expression, promotion of inflammation and endothelial dysfunction, enhancement of surface adhesion molecules expression, LDL oxidation, metalloproteinase (MMP) production and consequently plaque rupture (Katsiki & Manes 2009). Based on these observations and evidence largely from epidemiological studies, investigation of various antioxidant substances, in particular vitamin E, has been conducted to determine their role in primary and/or secondary prevention of cardiovascular disease.

Vitamin E is best known for its effects on the cardiovascular system, as it inhibits platelet aggregation and adhesion, and smooth-muscle-cell proliferation, has an anti-inflammatory effect on monocytes, improves endothelial function and decreases lipid peroxidation (Kaul et al 2001). It also modulates the expression of genes that are involved in atherosclerosis (e.g. scavenger receptors, integrins, selectins, cytokines, cyclins) (Munteanu et al 2004). Its ability to reduce oxidative stress, both directly and indirectly as part of the antioxidant network, is of particular importance because oxidation of LDL is a key process in atherogenesis, enhancing foam-cell and early lesion formation (Terentis et al 2002).

Epidemiological and clinical studies

In 1946 Canadian physicians first reported that vitamin E could protect against coronary heart disease; however, it was not until the results of two very large human studies were published nearly 50 years later that the greater scientific community and the public started to take note of vitamin E. In 1993, the prospective Nurses' Health Study and the Health Professionals' Follow-up study both reported that, compared to non-users, vitamin E supplementation at a dose of at least 100 IU for at least 2 years significantly reduced the risk of coronary disease by an estimated 40% (Rimm et al 1993, Stampfer et al 1993).

The prospective Nurses' Health Study followed 87,245 women aged 34–59 years without known coronary disease over 8 years and found that those women with the highest intake of vitamin E had the lowest relative risk of non-fatal myocardial infarction (MI) or death from coronary disease, compared to those with the lowest intake (Stampfer et al 1993). Interestingly, short-term use or dietary intake alone did not produce the same significant reduction. The Health Professionals' Follow-up study observed 39,910 men aged 40–75 years over 4 years and produced similar results, finding that long-term vitamin E (at least 100 IU/day) significantly reduced the relative risk of coronary disease compared to non-users (Rimm et al 1993).

Subsequently, a double-blind study conducted at Cambridge University, UK, and published in 1996 supported these results, but further suggested that higher doses could produce benefits more quickly and more dramatically (Stephens et al 1996). The placebo-controlled randomised study known as the Cambridge Heart Antioxidant Study (CHAOS) involved 2002 patients with angiographically proven coronary atherosclerosis, and compared the effects of two different strengths of alpha-tocopherol supplementation (400 IU and 800 IU)

and a placebo over a median of 510 days. Treatment with either dose of vitamin E was seen to reduce the risk of cardiovascular death and non-fatal MI by over 75%, with effects established after 12 months.

In 1999, results from the large GISSI trial were published, which were conflicting results (Albert et al 1999, GISSI 1999). The trial, which involved 11,324 patients who had recently survived a MI (< 3 months), investigated the effects of three different treatment protocols compared to a placebo: 1 g omega-3 fatty acid/day, 300 IU synthetic vitamin E/day, fish oils plus vitamin E/day, or a placebo. The four groups were observed for nearly 4 years for cardiovascular disease morbidity and mortality. Results showed that the fish-oil treatment groups had significantly decreased combined end-points of death, non-fatal MI and stroke over this time, whereas the vitamin E treatment produced little effect. The trial has since been criticised because the form of vitamin E used was synthetic and the dose was relatively low compared to doses in other studies involving patients with preexisting disease.

To date, 18 different randomised studies in the peer-reviewed literature have evaluated vitamin E in people at risk of CVD or with clinically diagnosed CVD (Katsiki & Manes 2009). The larger studies — GISSI (GISSI 1999), Women's Antioxidant Cardiovascular Study (WACS) and Alpha-Tocopherol Beta-Carotene (ATBC) Cancer Prevention study — have resulted in several published papers as researchers analyse effects in sub-groups or results are re-evaluated using different models. Overall, 8 randomised studies have tested vitamin E as a sole treatment, four studies have studied vitamin E in combination with vitamin C supplementation, and six have used multiple vitamin combinations which included vitamin E. The dose of vitamin E administered varies considerably from 55 IU to 800 IU daily and in at least five studies, synthetic vitamin E was used. In general, studies using natural

Clinical note — Confusing results for vitamin E

To date, many in vitro, animal and epidemiological studies support the use of vitamin E in the prevention of cardiovascular disease (Clarke & Armitage 2002). However, intervention studies are equivocal. Many factors could account for the lack of benefit on the primary end-point in the majority of trials.

1. Dose selection

A closer look at the evidence shows that dose selection varies enormously from levels just above the RDI (50 mg/day) to large doses of 800 IU/day. Clinical research reveals that a daily dose of at least 400 IU is required for LDL to become less susceptible to oxidation (Brockes et al 2003) and an effective threshold dose may be as high as 800 IU/day (Jialal & Devaraj 2005a).

2. Biomarkers of oxidative stress

Just as the statin trials investigate subjects with high cholesterol levels rather than the general population, it can reasonably be assumed that antioxidant treatment is best suited to those people with increased oxidative stress rather than the general population, yet researchers consistently fail to consider this as a biochemical basis for patient inclusion (Meagher 2003). The levels of oxidised amino acids in urine and plasma can reflect those in tissues and identify people with high levels of oxidative stress; this may be one method of subject selection (Heinecke 2002).

3. Type of supplement

In the specific case of vitamin E, the form of tocopherol used is crucial, as synthetic forms have less biological activity than RRR D-alpha-tocopherol. According to a 2002 FAO/WHO report, cross-country correlations between coronary heart disease mortality in men and the supply of vitamin E homologues acrsoss 24 European countries shows a highly significant ($P < 0.001$) correlation for D-alpha-tocopherol, whereas all other forms of vitamin E do not achieve statistical significance.

In the last few years, it has further been proposed that the lack of efficacy of commercial tocopherol preparations in some clinical trials may be due to the absence of other natural tocopherols, primarily gamma- and delta-tocopherol. Preliminary studies provide some support for this view (Jialal & Devaraj 2005a, Saldeen & Saldeen 2005). Studies using different mixtures of alpha-, beta-, gamma- and delta-tocopherol have found that a mixture of gamma-, delta- and alpha-tocopherol with the ratio of 5:2:1 have a much better antioxidant effect than alpha-tocopherol alone. This mixture is similar to that found in nature. In human and animal studies, the mixed tocopherol preparation also had much more favourable effects on constitutive NO synthase (ecNOS) and superoxide dismutase activity than alpha-tocopherol, and in a rat model was more effective in decreasing platelet aggregation and inhibiting thrombus formation. A mixed tocopherol preparation is also superior to alpha-tocopherol in terms of myocyte protection (Chen et al 2002).

4. Plasma vitamin E levels

The measurement of plasma vitamin E levels in the supplemented groups has been inconsistent in the studies, so it is uncertain whether levels significantly rose in response to treatment and subjects were compliant. For example, in the CHAOS, ASAP, ASAP follow-up and SPACE studies, a significant increase in the plasma antioxidant levels was reported and all studies found a benefit on the primary end-point, whereas measurement of plasma levels has been inconsistent in the negative studies (Jialal & Devaraj 2005a).

Clearly, the optimal form/s, dosage regimen, duration of use and subpopulation best suited to primary and secondary preventative treatment still need to be clarified with future trials.

TABLE 1 Summary of Positive Findings from Randomised Studies of Vitamin E in Primary or Secondary CVD Prevention

Name of study	Prevention goal	Number of subjects	Characteristics	Daily intervention	Findings
CHAOS (Stephens et al 1996)	Secondary	2002	Coronary disease	Natural vitamin E (400 IU or 800 IU)	Vitamin E reduced risk of cardiovascular death and non-fatal MI by over 75%.
SPACE (Boaz et al 2000)	Secondary	2198	End-stage renal disease – people on haemodialysis with preexisting CV event	Natural vitamin E (800 IU)	Vitamin E caused a 50% reduction in cardiac events.
CLAS (Azen et al 1996)	Secondary	146	Non-smoking 40–59-year-old men with previous coronary artery bypass graft surgery	Vitamin E (< or > 100 IU) and vitamin C (< or > 250 mg)	Higher vitamin E intake was associated with less carotid IMT progression compared with low vitamin E users in people not treated with colestipol.
ASAP (Salonen et al 2003)	Primary	520	Smoking/non-smoking men and postmenopausal women aged 45–69 years with elevated serum cholesterol	Twice daily either (136 IU) of D-alpha-tocopherol, 250 mg of slow-release vitamin C, a combination of these, or a placebo, for 3 years	The proportion of men with progression of carotid atherosclerosis was reduced by 74% with combination of vitamins E and C compared to the placebo; no significant effect was seen in women.
ASAP follow-up (Salonen et al 2003)	Primary	520	Smoking/non-smoking men and postmenopausal women aged 45–69 years with elevated serum cholesterol	Twice daily (136 IU) of D-alpha-tocopherol, 250 mg of slow-release vitamin C, or a placebo, for 6 years	Effect was still significant after a further 3 years: combined vitamins E and C continued to slow down atherosclerotic progression in hypercholesterolaemic men.
ATBC (Rapola et al 1996)	Primary: incidence of angina pectoris	29,134	Finnish male smokers aged 50–69 years with no history of MI	Synthetic vitamin E (55 IU), beta-carotene (20 mg), or both, or a placebo	Vitamin E was associated with a minor decrease in incidence of angina pectoris.
ATBC (Virtamo et al 1998)	Primary and secondary	29,134	Finnish male smokers aged 50–69 years with no history of MI	Synthetic vitamin E (55 IU), beta-carotene (20 mg), or both, or a placebo	Vitamin E decreased incidence of primary major coronary events by 4%; no effect on incidence of non-fatal MI; vitamin E decreased incidence of fatal coronary heart disease by 8%.

TABLE 1 Summary of Positive Findings from Randomised Studies of Vitamin E in Primary or Secondary CVD Prevention (*continued*)

Name of study	Prevention goal	Number of subjects	Characteristics	Daily intervention	Findings
ATBC (subset) (Leppala et al 2000)	Primary: prevention of incident and fatal subarachnoid, intracerebral haemorrhage, cerebral infarction and stroke	29,134	Finnish male smokers aged 50–69 years with no history of MI	Synthetic vitamin E (55 IU), beta-carotene (20 mg), or both, or a placebo	Vitamin E prevented ischaemic stroke in high-risk hypertensive patients.
WACS (Cook et al 2007)	Secondary	8171	Women with CVD or at least 3 risk factors	Vitamin C (500 mg/day), natural vitamin E (600 IU every other day), and beta-carotene (50 mg every other day)	Vitamin E significantly reduced incidence of stroke and produced a marginally significant reduction in the primary outcome (a combination of MI, stroke, coronary revascularisation, or CVD death) in a prespecified subgroup of women with prior CVD.
IEISS (Singh et al 1996)	Secondary	125	Patients with suspected acute MI	Vitamin E (400 mg), vitamin A (50,000 IU), vitamin C (1000 mg), beta-carotene (25 mg)	Treatment reduced mean infarct size, angina pectoris and total arrhythmias; poor left ventricular function occurred less often with antioxidants; cardiac end points were significantly less in the antioxidant group (20.6% vs 30.6%, respectively).
Fang et al 2002	Secondary	40	After cardiac transplantation	Twice daily vitamin C (500 mg) plus vitamin E (400 IU)	Supplementation with vitamins C and E retarded early progression of transplant-associated coronary arteriosclerosis compared to the placebo.

TABLE 2 Summary of Negative Findings from Randomised Studies of Vitamin E in Primary or Secondary CVD Prevention

Name of study	Prevention goal	Number of subjects	Characteristics	Daily intervention	Results
GISSI (Albert et al 1999)	Secondary	11,324	Post-MI	Synthetic vitamin E (300 mg/day), fish oils (1 g/day), combination of fish oil and vitamin E, or a placebo	There was no significant reduction in the combined end-points of death, non-fatal MI and stroke.
GISSI (Marchioli et al 2006)	Secondary	8415	Post-MI patients without CHF at baseline	Synthetic vitamin E (300 mg/day), fish oils (1 g/day), combination of fish oil and vitamin E, or a placebo	Vitamin E treatment was associated with a significant 50% increase of CHF in patients with left ventricular dysfunction (ejection fraction < 50%).
HOPE (Yusuf et al 2000)	Primary and secondary	9541	2545 women and 6996 men 55 years of age or older who were at high risk of cardiovascular events because they had cardiovascular disease or diabetes in addition to one other risk factor	Natural vitamin E (400 IU), and a placebo or angiotensin-converting-enzyme inhibitor (ramipril), or both	There was no significant effect on the primary outcome, which was a composite of MI, stroke and death from cardiovascular causes.
MICRO-HOPE (Lonn et al 2005)	Secondary	3654	Middle-aged and elderly people with diabetes and CV disease and/or additional coronary risk factor(s)	Vitamin E (400 IU) for an average of 4.5 years	Vitamin E had no effect on CV outcomes or nephropathy.
PPP (de Gaetano 2001)	Primary	4495	Those at risk of CVD: people with hypertension, hypercholesterolaemia, diabetes, obesity, family history of premature MI, or the elderly	Vitamin E (300 mg)	There was no significant reduction in CV events.
VEAPS (Hodis et al 2002)	Primary	353	Elevated LDL-C	Vitamin E (400 IU)	Significantly reduced circulating oxidized LDL and LDL oxidative susceptibility. Vitamin E supplementation did not reduce the progression of carotid artery far-wall intima-media thickness over a 3-year period.
ATBC (subset) (Rapola et al 1997)	Secondary	1862	Finnish male smokers with previous MI	Synthetic vitamin E (55 IU), beta-carotene (20 mg), or both, or a placebo	Risk of fatal coronary heart disease increased in groups receiving either beta-carotene or vitamin E and beta-carotene. There was a non-significant trend of increased deaths in the vitamin E group.

TABLE 2 Summary of Negative Findings from Randomised Studies of Vitamin E in Primary or Secondary CVD Prevention (*continued*)					
Name of study	**Prevention goal**	**Number of subjects**	**Characteristics**	**Daily intervention**	**Results**
HPS (Parkinson Study Group 2002)	Secondary	20,536	High CVD risk: coronary disease, other occlusive arterial disease, or diabetes	Vitamin E (600 mg), vitamin C (250 mg), beta-carotene (20 mg)	There were no significant differences in all-cause mortality, or in deaths due to vascular or non-vascular causes; no significant reduction in incidence of non-fatal MI, coronary death, non-fatal or fatal stroke or coronary or non-coronary revascularisation.
MVP (Tardif et al 1997)	Secondary: aimed to decrease incidence and severity of restenosis after angioplasty	317	Before and after coronary angioplasty	One month before angioplasty and for 6 months afterwards: multivitamins (30,000 IU beta carotene, 500 mg vitamin C, and 700 IU vitamin E) twice daily and/or probucol, or a placebo 12 hours before angioplasty given an extra 1000 mg probucol, 2000 IU vitamin E, or both, or a placebo	Multivitamin ineffective at reducing the rate of restenosis.
SUVIMAX (Zureik et al 2004)	Primary	1162	Healthy population	Vitamin C (120 mg), vitamin E (30 mg), beta-carotene (6 mg), selenium (100 micrograms), and zinc (20 mg)	There was no beneficial effect on carotid atherosclerosis and arterial stiffness.

vitamin E tend to produce positive results, showing a benefit on cardiovascular outcomes. Additionally, randomised trials conducted in people with established CVD were also more likely to report a cardioprotective effect than primary prevention studies (Katsiki & Manes 2009).

Restenosis

Restenosis is a major limitation to the long-term success of angioplasty. Therefore, measures that prevent or delay this occurrence are being investigated to extend the beneficial effects of the procedure.

Studies in experimental models have shown that vitamin E helps to stabilise atherosclerotic plaque after angioplasty and favours vascular remodelling, thereby suggesting that it may be of benefit in preventing or slowing restenosis (Orbe et al 2003). An early double-blind study using oral synthetic vitamin E (1200 IU) for 4 months found that treatment did not significantly reduce the rate of restenosis after percutanous transluminal coronary angioplasty; however, a minor reduction was detected (DeMaio et al 1992).

The MVP trial by Tardif et al, which aimed to decrease the incidence and severity of restenosis after angioplasty, involved 317 patients due for coronary angioplasty who were given a combination of vitamins, including vitamin E (Tardif et al 1997). One month before surgery and for 6 months afterwards, patients were administered multivitamins (30,000 IU beta carotene, 500 mg vitamin C, and 700 IU vitamin E) twice daily and/or probucol, or a placebo. Twelve hours before angioplasty, they were given an extra 1000 mg probucol, 2000 IU vitamin E or both, or placebo. Treatment with probucol was effective, whereas the multivitamin treatment did not significantly reduce the rate of restenosis.

Angina pectoris

Low-dose vitamin E supplements (50 mg/day) produce a minor decrease in the incidence of angina pectoris in smokers without previous coronary heart disease, according to a RCT (Rapola et al 1996). A smaller study of 29 subjects with variant angina identified six patients who did not respond to calcium-channel blockers and had lower plasma levels than normal but who responded positively to supplementation with 300 mg/day vitamin E. Treatment resulted in a significantly reduced incidence of angina episodes (Miwa et al 1996). Several years later, the same research group identified a transcardiac reduction in plasma vitamin E concentrations concomitant with lipid peroxide formation, suggesting that oxidative stress and vitamin E depletion may be involved in the pathogenesis of coronary artery spasm (Miwa et al 1999).

Nitrate tolerance

Vitamin E supplements (200 mg three times daily) prevented nitrate tolerance when given concurrently with transdermal nitroglycerin (NTG 10 mg/24 hours), according to one randomised, placebo-controlled study in which 24 patients with ischaemic heart disease were compared with 24 healthy volunteers over a 6-day period (Watanabe et al 1997). New research indicates that continuous NTG infusion causes vitamin E depletion, as well as nitrate tolerance, and as the vitamin E levels continue to fall, NTG tolerance becomes greater (Minamiyama et al 2006).

Hypertension

Vitamin E supplementation may reduce blood pressure, LDL oxidation and improve endothelial dysfunction in hypertension, according to current research.

An early double-blind, placebo-controlled study found that DL-alpha-tocopherol nicotinate (3000 mg) significantly reduced SBP from 151.0 to 139.2 mmHg within 4–6 weeks in hypertensive subjects; however, DBP remain unchanged (Iino et al 1977). More recently, long-term vitamin E (200 IU/day) was shown to decrease SBP by 24% in mildly hypertensive patients compared with a 1.6% reduction with a placebo, according to a triple-blind placebo-controlled study conducted over 27 weeks (Boshtam et al 2002). The study involved 70 hypertensive patients (SBP 140–160 mmHg; DBP 90–100 mmHg) aged 20–60 years without other cardiovascular risk factors. Besides reducing SBP, DBP was reduced by 12.5% compared with 6.2% with a placebo.

Some studies have revealed that hypertensive patients have a higher susceptibility to LDL oxidation than normotensive subjects and, therefore, increased atherogenic potential. One study measured the effect of vitamin E (400 IU/day) on the resistance of LDL to oxidation in 47 volunteers (Brockes et al 2003). Comparisons made before and after 2 months' supplementation showed that vitamin E caused a significant increase in the lag time in normotensive and hypertensive patients, ultimately bringing hypertensive patients up to the same point as the healthy controls.

All-cause mortality (ACM)

There is substantial research indicating benefits for vitamin E supplementation in the treatment and prevention of various diseases, but regardless of these benefits, two meta-analyses have drawn the conclusion that vitamin E supplementation increases ACM (Miller et al 2005, Bjelakovic et al 2007). These findings have been unexpected and widely criticised, as they are based on results of smaller studies of variable quality, often involving people with chronic disease and sometimes testing vitamin E as part of a multinutritional intervention and not as a stand-alone treatment. Based on recent re-analysis of the data by Berry et al (2009) and Gerss and Kopcke (2009), which are discussed below, the evidence is not convincing that vitamin E supplementation increases mortality.

In 2005, Miller et al (2005) published a meta-analysis of the dose–response relationship between vitamin E supplementation and total mortality using data from 19 RCTs consisting of a large study population (n = 135,967). A dose–response analysis showed a statistically significant relationship between vitamin E dosage and all-cause mortality. The authors suggested caution with doses of

Clinical note — LDL oxidation and vitamin E
Oxidative stress affects lipid metabolism by producing an oxidised LDL that has greater atherogenic potential than its original form. In the past, attention focused on investigating various antioxidants, such as vitamin E, for their ability to prevent LDL oxidation. In recent years, researchers have started to focus on identifying the biological oxidants responsible for initiating oxidation of LDL within the human arterial wall and on a better understanding of what makes oxidised LDL pro-atherogenic. In 2003, in vitro testing with LDL discovered that myeloperoxidase is a pathway that promotes LDL oxidation in the human artery wall, although others are also likely to exist. It is noteworthy that vitamin E failed to inhibit LDL oxidation by myeloperoxidase in vitro (Heinecke 2003), although it does reduce LDL oxidation in animals and humans when given in doses well above RDI (Brockes et al 2003). If further testing confirms these results, it may mean that vitamin E reduces LDL oxidation in vivo, mainly through its role in the antioxidant network. In other words, its ability to regenerate antioxidants such as vitamin C, coenzyme Q10 and selenium may be more important than its direct antioxidant action.

400 IU/day or higher, while acknowledging that the high-dose studies (≥ 400 IU/day) analysed in the report were often small and performed in patients with chronic diseases.

This meta-analysis has several serious flaws and has been criticised on a number of accounts, inspiring over 40 letters to the journal's editor and hundreds of emails and telephone calls to the authors (Jialal & Devaraj 2005b). In summary, these responses centre on six major flaws. First, results from 12 clinical studies that reported fewer than 10 deaths each were excluded from the meta-analysis, which created the appearance of bias and would have given an artificial weight to studies in which more people died. Second, the meta-analysis included trials of different designs, treatment times, doses, combinations and end-points. Pooling information together from such heterogeneous studies was considered inappropriate. Third, subjects in many studies had significant chronic diseases, such as Parkinson's disease, end-stage renal disease, coronary artery disease, diabetes mellitus and Alzheimer's dementia, which would have influenced their mortality risk. This also means that the results do not necessarily apply to healthy adults taking these supplements. Next, studies used different forms of vitamin E (natural and synthetic) and sometimes used vitamin E in combination with other nutrients; however, results of all these studies were pooled and not separated. Furthermore, subject adherence to the treatment protocol was considered in only one study (CHAOS). Lastly, the use of some statistical models has been questioned.

In 2007, Bjelakovic et al conducted a meta-analysis using data from 68 randomised trials involving 232,606 adults that compared beta carotene, vitamin A, vitamin C (ascorbic acid), vitamin E and selenium, either singly or combined, to a placebo or to no intervention (Bjelakovic et al 2007). When all trials of antioxidant supplements were pooled, there was no significant effect on mortality for vitamin E given singly in high (≥ 1000 IU) or low dose (< 1000 IU). After exclusion of high-bias risk (studies with heterogeneity) and selenium trials, vitamin E given singly or combined with other antioxidants significantly increased mortality, with an estimate of increased mortality of about 5%. A closer look at the details of the study reveals that, of the 815 trials originally identified, 405 trials were excluded from the meta-analysis because mortality was zero (n = 40 000). Vitamin E was administered in doses ranging from 10 to 5000 IU daily, and populations studied were either healthy (primary prevention trials) or had a variety of established diseases such as cancer, CVD, renal disease, hepatitis, systemic lupus erythematosus, heart failure, cirrhosis, gastritis, MI or macular degeneration.

Gerss and Kopcke (2009) recently re-analysed the available data to double-check the findings and concluded that the use of different methodological approaches to meta-analysis will yield contradictory results, with some statistical models finding an association and others not. They used the same data as that described in the Miller et al (2005) meta-analysis and augmented it with an additional 10 trials (2495 additional participants receiving vitamin E doses from 136 to 5000 IU/day). Moreover in two of the originally included trials, updated results of mortality at longer periods of follow-up were available.

More specifically, hierarchical logistic regression analyses confirmed the former results, showing an increased mortality of patients receiving high-dose vitamin E, whereas application of a traditional methodological approach to meta-regression found that in certain trials increased mortality was not due to high-dose vitamin E but could be explained by a higher proportion of male subjects compared to other trials (Gerss & Kopcke 2009). Overall, the causal relationship of vitamin E supplementation and increased ACM is questionable and, in particular, high-dose vitamin E supplementation cannot be regarded as 'proved' to increase mortality.

Similar findings were obtained by Berry et al (2009), who applied a Bayesian meta-analytic method to synthesise results from previous clinical trials of vitamin E. They used data from studies in the Miller et al (2005) meta-analysis, appended by 10 more recent studies and concluded that vitamin E intake is unlikely to affect ACM, regardless of dose.

Re-evaluation of data from the original Framingham Heart Study has also failed to find an association between vitamin E supplementation and increased risk of ACM (Dietrich et al 2009). The Framingham Heart Study (n = 4270) began enrolling in 1948 to investigate the association between supplemental vitamin E and the 10-year incidence of CVD and ACM. Eleven percent of people participating in the study used vitamin E supplements at baseline and the most commonly consumed dose was 300–500 IU/day. In all statistical models, age, diabetes and treatment for blood pressure were significant positive

predictors of CVD and ACM, whereas no statistically significant associations were found between vitamin E supplement intake and CVD and ACM. In secondary analyses, the associations of vitamin E dose and duration of use with CVD and ACM were assessed. Once again, no statistically significant associations were observed in any of the analyses for CVD or ACM. The effect of potential confounders, such as use of aspirin, anti-cholesterol treatment and multivitamins, were minimised using multivariate models which did not change the results.

Parkinson's disease (PD)

Based on experimental and clinical data, it is well established that oxidative stress and lipid peroxidation is increased in the substantia nigra of people with PD and this may play an important role in the disease's aetiology. Vitamin E has therefore been the focus of research as a potential treatment. Using both in vitro and in vivo experimental model systems for PD, studies have demonstrated both vitamin-E-mediated protection and lack of protection (Fariss & Zhang 2003). Similarly, inconsistent results have been obtained for vitamin E supplementation in the prevention and treatment of clinical PD. An open study using high doses of both tocopherol (3200 IU/day) and ascorbic acid (3000 mg/day) delayed the use of levodopa or dopamine agonists for 2 years in subjects with early PD (Fahn 1992). In contrast, the Deprenyl and Tocopherol Antioxidative Therapy of Parkinsonism (DATATOP) study found no effect on the progression of disability with a dose of alpha-tocopherol 2000 IU/day (Parkinson Study Group 1996). The same study found vitamin E had no effect on mortality (Parkinson Study Group 1998).

Clinical note — Neurodegenerative disease and oxidative stress

Neurodegenerative diseases are defined by the progressive loss of specific neuronal cell populations and are associated with protein aggregates. A growing body of evidence suggests that oxidative stress plays a key role in the pathophysiology of neurodegenerative disorders such as Alzheimer's dementia and Parkinson's disease. Reactive oxygen species (ROS) are known to cause cell damage by way of three main mechanisms: lipid peroxidation, protein oxidation and DNA oxidation. Cells have developed several defence and repair mechanisms to deal with oxidative stress, and antioxidants such as vitamin E represent the first line of defence. In addition to its antioxidant properties, vitamin E can act as an anti-inflammatory agent, which may also be neuroprotective, and it regulates specific enzymes, thus changing the properties of membranes. The CNS is especially vulnerable to free-radical damage because compared to other tissues it has a high oxygen consumption rate, abundant lipid content and a relative deficit in antioxidant systems. While it remains unclear whether oxidative stress is the primary initiating event associated with neurodegeneration or a secondary effect related to other pathological pathways, a growing body of evidence implicates it as being involved in the propagation of cellular injury (Ricciarelli et al 2007).

Alzheimer's dementia and cognitive decline

The current standard of care for pharmacological management of the cognitive and functional disabilities of Alzheimer's dementia (AD) consists of a cholinesterase inhibitor and sometimes the addition of high-dose vitamin E (Bonner & Peskind 2002). The inclusion of vitamin E is largely based on a 1997 double-blind study that compared a large dose of synthetic vitamin E (1000 IU twice daily) with selegiline (5 mg twice daily) and placebo in a group of patients with moderately severe AD. The 2-year study found that vitamin E significantly slowed down the progression of the disease, delayed institutionalisation and increased survival rate (Sano et al 1997).

Since the 1997 study, numerous dietary and intervention studies have sought to clarify whether vitamin E is protective against the development of various forms of dementia or can slow its progression.

Prevention

Higher plasma vitamin E levels are associated with a significantly reduced risk of cognitive impairment and dementia in older adults. Protection is most consistently seen with vitamin E from food sources, but not always from vitamin E supplements (Cherubini et al 2005, Engelhart et al 2002, Morris et al 2005). According to one study, for every 5 mg/day increase in vitamin E intake, a significant 26% reduction in risk is possible (Morris et al 2005). It now appears that alpha-tocopherol is not the only form of vitamin E exhibiting protective effects. A comparison between the four different tocopherols found naturally in food identified that gamma-tocopherol is also beneficial.

Intervention studies using supplements have produced mixed results and focus on alpha-tocopherol only. The Cache County Study was a large study of 4740 people aged 65 years or older that found a combination of vitamins E (400 IU/day) and C (500 mg/day) taken for at least 3 years was associated with a reduced incidence of AD (Zandi et al 2004). No protective effects were seen when vitamin E or C was taken alone. In the Honolulu/Asia Aging Study, long-term use of vitamin E and C supplements was associated with an 88% reduction in the frequency of subsequent vascular dementia and appeared to improve cognitive function in later life; however, a protective effect against AD was not observed (Masaki et al 2000). A lack of association between dietary or supplemental vitamin E and risk of AD in elderly subjects was also found in the Washington Heights/Inwood Columbia Aging Project (WHICAP), which involved 980 older subjects (Luchsinger et al 2003). It must be noted that dietary intakes were assessed in this study with a limited food frequency questionnaire, which is likely to be less accurate than the more detailed surveys used in some other studies.

Slowing progression

In contrast to the positive 1997 study, a more recent study involving 769 subjects with possible or probable AD using the same dose found no significant effects in patients with mild cognitive impairment and no change to the rate of progression to AD over a 3-year period (Petersen et al 2005).

A Cochrane Systematic Review published in 2008 concluded that there is no evidence of efficacy for vitamin E in the treatment of AD or progression of mild cognitive impairment to AD. However, they used data from only two randomised studies, so further research is required to clarify the issue (Isaac et al 2008).

Immunity in the elderly

Immune cell function is influenced by the oxidant and antioxidant balance, so antioxidant supplements have been investigated clinically for their ability to enhance immune responses (Meydani et al 1998). Increased markers of T-cell-mediated immunity were enhanced with all doses of synthetic vitamin E tested, according to a randomised, double-blind study of 78 healthy elderly subjects. Doses used were 60, 200 and 800 mg/day for 4 months, with best overall responses obtained with the 200 mg dosage (Meydani et al 1997). Another double-blind study found no significant changes to either cellular or humoral immune responses with a low dose of 100 mg/day of synthetic vitamin E taken over 3 months (de Waart et al 1997).

Common cold

Low-dose vitamin E supplementation (50 mg/day) was found to reduce the incidence of the common cold by 28% in a subgroup of men enrolled in the ATBC Cancer Prevention study (Hemila et al 2006). Participants were older city-dwelling men (≥ 65 years) who smoked only 5–14 cigarettes/day. More recently, researchers re-evaluated the data and found that the effect of vitamin E diverged, depending on location of dwelling and smoking status. Among city-dwelling men considered to be low–moderate level smokers (5–14 cigarettes/day), vitamin E significantly reduced common-cold risk, whereas among those smoking more and living away from cities, vitamin E increased common-cold risk. It appears that different modifying factors have an influence on whether vitamin E supplementation has beneficial or harmful effects.

Haemodialysis (HD)

Vitamin E supplementation may offer several benefits to patients on HD, who typically experience high levels of oxidative stress, as there is some evidence that supplementation reduces oxidative stress and LDL oxidability in this population (Badiou et al 2003, Diepeveen et al 2005, Galli et al 2001, Giray et al 2003). The SPACE study by Boaz et al (2000) found that high-dose vitamin E supplementation (natural vitamin E 800 IU/day) caused a 50% reduction in cardiac events. This is a highly significant outcome and worthy of further investigation.

HD patients also experience cramps, which appeared to respond to vitamin E supplementation according to a placebo-controlled, double-blind study of 60 subjects (Khajehdehi et al 2001). Treatment with a vitamin E dose of 400 mg/day for 8 weeks resulted in a 54% reduction in cramps, which increased to a 97% reduction when combined with vitamin C (250 mg/day). The benefits were not significantly associated with age, sex, aetiology of end-stage renal disease, serum electrolytes or HD duration, but showed a positive correlation ($P = 0.01$) with the type of therapy used.

According to one small study, vitamin E supplementation (500 mg/day) allowed for a reduction in erythropoietin dose (from 93 to 74 IU/kg/week) while maintaining stable haemoglobin concentrations (Cristol et al 1997).

Premenstrual syndrome (PMS)

Treatment with D-alpha-tocopherol (400 IU/day) over three menstrual cycles significantly alleviated some affective and physical symptoms of PMS according to one randomised double-blind study (London et al 1987). Symptoms of anxiety, food craving and depression responded to active treatment, whereas effects on other measured parameters such as weight gain were not significant.

An earlier study of 75 women with benign breast disease found that D-alpha-tocopherol (150–600 IU/day) significantly decreased some symptoms of PMS compared with a placebo; however, the study involved subjective patient evaluation, which may have influenced the findings (London et al 1983).

Dysmenorrhoea

According to two randomised placebo-controlled studies, taking 200 IU vitamin E twice daily or 500 IU daily, starting 2 days before menstruation and continuing for the first 3 days of bleeding, seems to reduce menstrual pain severity and duration and to decrease blood loss in teenaged girls with primary dysmenorrhoea (Ziaei et al 2001, 2005). Beneficial effects can be seen after 2 months and reach maximal effect after 4 months.

Intermittent claudication

A Cochrane Review of five placebo-controlled studies including a total of 265 volunteers (average age 57 years) concluded that, although further research is required to determine its effectiveness, vitamin E may have beneficial effects in intermittent claudication with no serious side effects (Kleijnen & Mackerras 2000). Treatment duration varied from 12 weeks to 18 months, and dosage regimens varied between the studies, which were considered generally small and of poor quality. A closer look at the evidence suggests that doses of at least 600 IU/day for a minimum of 12 weeks are required.

More recently, a randomised, double-blind study with vitamin E (400 IU/day) found no beneficial effects on perceived pain or treadmill-walking duration in people with claudication (Collins et al 2003).

A small study of 16 patients with stable claudication revealed that administration of vitamin E (200 mg/day) and vitamin C (500 mg/day) for 4 weeks reduces oxidative stress in this population,

and therefore may also have an effect on the remote ischaemia–reperfusion damage (Wijnen et al 2001).

Cancer

Most of the epidemiological evidence suggests that vitamin E and other antioxidants decrease the incidence of certain cancers. Based on these observations, numerous prospective and intervention studies have been conducted in various populations. Very often, vitamin E is used in combination with other antioxidant nutrients, and sometimes the form of tocopherol administered is not stated, thereby making it difficult to interpret study findings.

A review that systematically evaluated the scientific literature using guidelines developed by the US Preventative Services Task Force concluded that there is evidence to suggest that those individuals with higher serum vitamin E levels or who are receiving vitamin E supplementation have a decreased risk of some cancers, including lung, prostate, stomach and gastrointestinal carcinoma (Sung et al 2003). As can be expected, study design, differing treatment dose (nutritional levels or higher), form of vitamin used and population studied (general or high risk) had an influence on outcomes. Since then, several new studies have been published that cast doubt on the cancer protective effects of vitamin E for the general population. However, it seems likely that certain subpopulations (e.g. the poorly nourished) may benefit, and that lifestyle factors modify responses to supplementation (e.g. smoking). Recent research further suggests that differences in telomere length may be another factor affecting individuals' responses to vitamin E supplements (Shen et al 2009)

All cancers

A large study of nearly 30,000 subjects was carried out in Linxian, China. It tested four combinations of vitamins and minerals (retinol and zinc; riboflavin and niacin; vitamin C and molybdenum; and beta-carotene, vitamin E and selenium) over a 5-year period in a population with a persistently low intake of several micronutrients (Blot et al 1995). Although no statistically significant effect on cancer incidence was achieved by any intervention, secondary analysis showed that the combination of selenium, beta-carotene and alpha-tocopherol was associated with a statistically significant lower total mortality rate, a 13% reduction (borderline significant) in total cancer mortality rate and a statistically significant lower mortality rate from stomach cancer (a major cancer in Linxian).

Results from the SUVIMAX study suggest that protective effects of vitamin E may be gender specific (Zureik et al 2004). In this trial, antioxidant supplementation (vitamin C 120 mg, vitamin E 30 mg, beta-carotene 6 mg, selenium 100 micrograms, and zinc 20 mg) was associated with a lower cancer incidence in men, but not in women. It is possible that men in the SUVIMAX trial benefited from supplementation due to their lower baseline levels of antioxidants.

More recently four large studies have found that vitamin E supplementation has no protective effect against cancer incidence. The MRC/BHF study of 20,536 UK adults aged 40–80 years with coronary disease, other occlusive arterial disease, or diabetes found that a daily antioxidant supplement containing 600 mg vitamin E, 250 mg vitamin C and 20 mg beta-carotene produced no significant reduction in the incidence of cancer or in all-cause mortality (Parkinson Study Group 2002). The HOPE-TOO study, which used long-term natural vitamin E (400 IU/day) as a stand-alone supplement, failed to find a protective effect against cancer incidence or cancer deaths in people with preexisting vascular disease or diabetes mellitus (Lonn et al 2005). Long-term use of natural vitamin E (600 IU) taken on alternate days provided no overall benefit for cancer incidence or total mortality in a large randomised study involving 39,876 healthy women of at least 45 years of age (Lee et al 2005).

Results from 7627 women free of cancer at baseline in the Women's Antioxidant Cardiovascular Study (WACS) found that long-term use (average 9.4 years) of vitamin C (500 mg/day), natural vitamin E (600 IU every other day) and beta-carotene (50 mg every other day) was not significantly associated with lowered incidence of total cancer or cancer mortality for any of the tested antioxidants (O'Donnell et al 2009).

When data was evaluated for effects on site-specific cancers, women receiving vitamin E supplements had a reduced risk (but not statistically significant) for colorectal cancer compared with the placebo group. This was largely due to a reduced risk of colon cancer. However, there was no statistically significant association of vitamin E supplementation with rectal or other cancers. Further subgroup analysis revealed women in the vitamin E supplement group who currently smoked or had smoked in the past had lower rates of cancer death than those who never smoked.

Urinary tract cancer

Analysis of data from the ATBC Cancer Prevention Study, which tested synthetic vitamin E (50 mg/day) and beta-carotene (20 mg/day) in male Finnish smokers aged 50–69 years (n = 29,133) found neither supplement affected the incidence of urothelial cancer or the incidence of renal cell cancer (Virtamo et al 2000).

Aerodigestive cancers

Smoking and alcohol consumption are the major risk factors for upper aerodigestive tract cancers, and observational studies indicate a protective role for fruits, vegetables and antioxidant nutrients (Wright et al 2007). Analysis of data from the ATBC Cancer Prevention Study testing long-term supplementation with synthetic vitamin E (50 mg/day) and beta-carotene (20 mg/day) in male Finnish smokers aged 50–69 years (n = 29,133) found no effect of either agent on the overall incidence of any upper aerodigestive tract cancer nor any effect on mortality from these neoplasms.

Breast cancer

Mixed results have been obtained for vitamin E in the primary prevention of breast cancer, although a recent study has detected a modest protective

effect against recurrence of breast cancer and disease-related mortality in postmenopausal women previously diagnosed with the disease (Fleischauer et al 2003). Protective effects were established after 3 years' use, according to the study.

Ovarian cancer

Vitamin E supplements were protective against the incidence of ovarian cancer whereas consumption of antioxidants from diet was unrelated to risk according to another study (Fleischauer et al 2001). In analyses combining antioxidant intake from diet and supplements, vitamins C (> 363 mg/day) and E (> 75 mg/day) were associated with significant protective effects.

Colorectal cancer

Studies investigating the association between vitamin E and incidence of colorectal cancer have produced inconsistent results. Prospective studies have shown that high serum levels of vitamin E are protective; however, only one of three intervention studies has produced positive results (Stone & Papas 1997). These results are difficult to interpret, as the studies have been criticised for not adequately distinguishing between cancer incidence and adenoma recurrence.

In the WACS (n = 7627), women receiving natural vitamin E (600 IU every other day) had a reduced risk (but not statistically significant) of colorectal cancer compared with the placebo group. This was largely because of a reduced risk of colon cancer; however, there was no statistically significant association of vitamin E supplementation with rectal or other cancers (O'Donnell et al 2009). The ATBC study also detected a somewhat lower incidence of colorectal cancer in the alpha-tocopherol arm compared with the no alpha-tocopherol arm, but this was not statistically significant (Virtamo et al 2000).

Prostate cancer

The ATBC Cancer Prevention Study also provides information about the incidence of prostate cancer with long-term use of synthetic alpha-tocopherol (50 mg), beta-carotene (20 mg), both agents, or a placebo daily for 5–8 years (Albanes et al 2000). One of the most striking outcomes was a 32% decrease in the incidence of prostate cancer for volunteers receiving vitamin E (n = 14,564) compared to those not receiving it (n = 14,569) and a 41% reduction in mortality among men using vitamin E. Neither agent had any effect on the time interval between diagnosis and death (Heinonen et al 1998). The preventative effect of vitamin E on prostate cancer incidence was observed to be long term according to later analysis of postintervention effects (Virtamo et al 2003).

One study has identified a decrease in serum androgen concentrations associated with long-term alpha-tocopherol supplementation, suggesting this may be one of the factors contributing to the observed reduction in incidence and mortality of prostate cancer (Hartman et al 2001).

Currently, the US National Cancer Institute is conducting phases I, II and III chemoprevention trials for prostate, breast and colon cancers with vitamin E and the following micronutrients: isoflavones, lycopene, selenised yeast, selenomethionine, selenium, perillyl alcohol, folic acid, vitamin D, calcium and curcumin. It is suspected that the response to micronutrients may vary not only in magnitude but also in direction (Greenwald et al 2002).

Pancreatic cancer

Higher alpha-tocopherol concentrations may play a protective role in pancreatic carcinogenesis in male smokers according to the ATBC Cancer Prevention Study, which found men with the highest serum tocopherol levels had a lower pancreatic cancer risk (highest compared with lowest quintile) (Stolzenberg-Solomon et al 2009). Polyunsaturated fat, a putative pro-oxidant nutrient, modified the association such that the inverse alpha-tocopherol association was most pronounced in subjects with a high polyunsaturated fat intake. No associations were observed for dietary tocopherols and tocotrienols.

Other cancers

Further analysis of the ATBC Cancer Prevention Study found that neither synthetic vitamin E nor beta-carotene had a statistically significant effect on the rate of incidence of pancreatic carcinoma, the rate of mortality caused by this disease (Rautalahti et al 1999) or the occurrence of neoplastic changes in cases of atrophic gastritis (Varis et al 1998).

Adjunct with cisplatin

Bove et al (2001) made the observation that the neurotoxic presentation associated with cisplatin use was similar to that of vitamin E deficiency. They hypothesised that cumulative cisplatin use could induce vitamin E deficiency if patients' levels were not sufficiently high throughout treatment. To test the theory they started by measuring vitamin E in the plasma of five patients who developed severe neurotoxicity after cisplatin treatment and in another group of five patients before and after two or four cycles of cisplatin treatment. This produced preliminary data that supported the theory that inadequate vitamin E due to cisplatin treatment could be responsible for the peripheral nerve damage induced by free radicals (Bove et al 2001). Following this, four clinical trials were conducted to evaluate whether oral vitamin E supplementation could reduce the incidence of cisplatin-induced neurotoxicity. In all trials the incidence of chemotherapy-induced peripheral neuropathy was significantly reduced with vitamin E supplementation (Wolf et al 2008).

Oral vitamin E (300 mg/day), taken before cisplatin treatment and continued for 3 months after cessation of treatment, significantly reduced the incidence and severity of neurotoxicity according to a randomised study (n = 47), in which the incidence of neurotoxicity was significantly lower in the group receiving vitamin E (30.7%) compared to those receiving the placebo (85.7%; $P < 0.01$) (Pace et al 2003). Shortly afterwards, Argyriou et al (2005) conducted a randomised study of 31 patients

with cancer treated with six courses of cumulative cisplatin, paclitaxel or their combination regimens. Only 25% of patients randomly assigned to receive oral vitamin E (600 mg/day) during chemotherapy and for 3 months after its cessation developed neurotoxicity, compared to 73% in the control group. A year later in another randomised study, 30 patients scheduled to receive six courses of cumulative cisplatin-based regimens were randomly allocated to receive either vitamin E (600 mg/day) during chemotherapy and for 3 months after its cessation or no adjunctive therapy (controls). This study again found a significantly reduced incidence of neurotoxicity with vitamin E (21.4%) compared to controls (68.5%) ($P = 0.026$) (Argyriou et al 2006).

While no data was included on the long-term survival of the patients involved, studies undertaken have failed to show a detrimental effect from combining vitamin E with chemotherapy (Ladas et al 2004, Pace et al 2003). The results of these studies are promising in the chemotherapy setting.

Arthritis

High-dose vitamin E supplements may be effective in relieving pain in osteoarthritis (OA) and rheumatoid arthritis (RA), according to several double-blind studies, with some studies finding that the effects are as strong as with diclofenac. Vitamin E supplements have been studied in people with OA, RA, spondylitis ankylosis, spondylosis and psoriatic arthritis. Comparisons have been made to placebos and NSAIDs.

Osteoarthritis

According to an early crossover study (Machtey & Ouaknine 1978), 52% of OA patients experienced less pain when treated with vitamin E (600 mg/day) compared to a placebo. Several years later, a double-blind randomised study of 50 volunteers with OA confirmed these findings and showed that vitamin E (400 IU/day) was significantly superior to a placebo in relieving pain, increasing mobility and reducing analgesic requirements (Blankenhorn 1986). Symptoms of pain at rest, during movement or with applied pressure all responded to treatment with vitamin E.

Vitamin E supplementation (500 IU/day) did not alter the loss of cartilage volume in knee OA according to a 2-year, double-blind, randomised, placebo-controlled study of 138 patients (American College of Rheumatology clinical and radiographic criteria) (Wluka et al 2002). Additionally, symptoms did not improve. Vitamin E also failed to alleviate symptoms in a shorter, 6-month double-blind study using the same dose (Brand et al 2001) and symptoms of pain, stiffness and function did not change at the 1-, 3- or 6-month assessments.

Research has continued in recent years, so that by 2007 a systematic review by Canter, Wider and Ernst (2007) identified a total of seven RCTs that have tested vitamin E in OA: four trials compared the treatment with a placebo, two tested against diclofenac and one against vitamin A. Of these, two placebo-controlled trials demonstrated the effectiveness of vitamin E for pain. One trial was considered methodologically weak, but the second was more robust and indicated greater effectiveness both for the whole patient sample and for a subgroup with OA of the knee and hip. This is in contrast to two later studies that involved patients with OA of the knee and produced largely negative results. Two equivalence trials comparing vitamin E to diclofenac produced more positive outcomes and suggested similar effectiveness for the two treatments, with one study reporting a statistically significant superiority of vitamin E over diclofenac (Canter et al 2007). The authors of the review have claimed variable methodological rigour does not yet allow a definitive conclusion to be made about the effectiveness of vitamin E in OA.

Rheumatoid arthritis

According to several double-blind studies, a dose of 1200 mg/day vitamin E significantly reduces pain symptoms in people with RA, but not always morning stiffness.

A double-blind study of 42 RA patients who received vitamin E (600 mg twice a day) over 12 weeks showed that pain parameters were significantly decreased with active treatment compared to a placebo (Edmonds et al 1997). The same study also found no change in the Ritchie Articular Index, duration of morning stiffness, swollen joint count or laboratory parameters with vitamin E supplementation compared to a placebo. A further study using the same dose detected a significant inverse correlation between vitamin E levels and pain score, whereas morning stiffness and sedimentation rate were not affected (Scherak & Kolarz 1991).

Edmonds et al enrolled 42 patients with RA in a double-blind randomised study in which alpha-tocopherol (600 mg twice a day) was compared to a placebo for 12 weeks (Edmonds et al 1997). While laboratory measures of inflammatory activity and oxidative modification were unchanged with active treatment, pain parameters were significantly decreased after vitamin E treatment when compared with the placebo, suggesting that vitamin E may exert a small but significant analgesic activity independent of a peripheral anti-inflammatory effect.

More recently, a combination of standard treatment (intramuscular methotrexate, oral sulfasalazine and indomethacin suppository at night) and vitamin E (400 mg three times daily) was compared to standard treatment and a combination of antioxidants or to standard treatment alone (Helmy et al 2001). Standard treatment started to produce tangible improvements after 2 months, whereas additional treatment with either vitamin E or antioxidants improved symptoms more quickly (after 1 month).

Comparisons with pharmaceutical medication

After 3 weeks' treatment with either high-dose vitamin E (400 mg RRR-alpha-tocopherol acetate three times daily) or diclofenac sodium, a significant improvement in all assessed clinical parameters was observed in hospitalised patients with established chronic RA ($n = 85$), according to a randomised, double-blind parallel group trial (Wittenborg et al

1998). Duration of morning stiffness, grip strength and the degree of pain, assessed by a 10 cm visual analogue scale, reduced significantly with vitamin E as well as with diclofenac. Both treatments were considered to be equally effective by patients and physicians.

Menopausal symptoms

According to a review published by the Mayo Clinic in the USA, behavioural changes in conjunction with vitamin E (800 IU/day) is a reasonable initial approach for menopausal women with mild symptoms that do not interfere with sleep or daily function (Shanafelt et al 2002). The recommendation is based on a double-blind, randomised, placebo-controlled, crossover clinical trial that found that vitamin E (800 IU/day) was more effective than a placebo in controlling hot flushes in breast cancer survivors. Benefits have been confirmed in another double-blind, placebo-controlled trial, which found treatment with 400 IU vitamin E daily significantly reduced hot flush severity and daily frequency as reported by participants (Ziaei et al 2007).

Male infertility

Lipid-soluble antioxidants such as vitamin E have been studied for their effects in male reproductive physiology because the membranes of germ cells and spermatozoa are very sensitive to oxidation (Bhardwaj et al 2000, Bolle et al 2002).

According to three of four studies, oral vitamin E supplementation can effectively treat some forms of male infertility (Geva et al 1996, Kessopoulou et al 1995, Rolf et al 1999, Suleiman et al 1996). Doses varied from 200 mg/day to 800 mg/day.

Kessopoulou et al (1995) compared vitamin E (600 mg/day) to a placebo over 3 months in 30 healthy men with high levels of ROS generation in semen and a normal female partner. The randomised, crossover study found active treatment improved zona binding, thereby showing that vitamin E significantly improved the in vitro function of human spermatozoa. Geva et al (1996) studied men enrolled in an in vitro fertilisation program that previously had low fertilisation rates, and treated them with oral vitamin E (200 mg/day) for 3 months. After the first month, fertilisation rates increased significantly, from 19% to 29%. The same year, Suleiman et al (1996) treated asthenospermic patients with oral Vitamin E, which significantly decreased the malondialdehyde (MDA) concentration in spermatozoa and improved sperm motility. Of the 52 treated males, 11 (21%) impregnated their spouses and 9 of the spouses successfully continued to have normal-term deliveries, whereas two aborted in the first trimester. No pregnancies were reported in the spouses of the placebo-treated patients.

The negative study used high-dose oral vitamin C (1000 mg/day), and vitamin E (800 mg/day) was tested over 56 days in 31 men with asthenozoospermia (< 50% motile spermatozoa) and normal or only moderately reduced sperm concentration ($> 7 \times 10^6$ spermatozoa/mL) (Rolf et al 1999).

Dermatological conditions

Vitamin E is used both as an oral supplement and as a topical preparation in a variety of dermatological conditions. It is a popular ingredient in many moisturising preparations used to: alleviate dry and cracked skin; assist in the repair of abrasions, burns, grazes and skin lesions; prevent stretch marks; and diminish scar tissue. Vitamin E oil is used as a stand-alone preparation or incorporated into a cream or ointment base for these purposes.

Sunburn protection

Topical application of 1% alpha-tocopherol provided significant protection against erythema and sunburn in an experimental model. When combined with 15% ascorbic acid, the protective effect was enhanced (Lin et al 2003). Further improvements were seen when ferulic acid was added to the alpha-tocopherol (1%) and ascorbic acid (15%) solution, as this substance improves chemical stability of the antioxidants and doubles the photoprotective effect (Lin et al 2005).

Once again, it appears that not all forms of vitamin E exert a significant protective effect (McVean & Liebler 1999). According to an in vivo study, a 5% dispersion of alpha-tocopherol, gamma-tocopherol or delta-tocopherol in a neutral cream vehicle produced a statistically significant inhibition of thymine dimer formation, whereas alpha-tocopherol acetate and alpha-tocopherol methyl ether had no effect. Further research revealed that gamma-tocopherol and delta-tocopherol were five- to ten-fold less potent than alpha-tocopherol (McVean & Liebler 1997).

A comparison between topical vitamins E and C has demonstrated that vitamin E affords better protection against UVB radiation, whereas vitamin C is superior against UVA radiation (Baumann & Spencer 1999).

Although most research has focused on topical use, oral administration of a combination of high-dose vitamins E and C increases the threshold to erythema. The first study to show that the systemic administration of vitamins E and C reduces the sunburn reaction in humans was a small, double-blind, placebo-controlled trial that used ascorbic acid (2 g/day) combined with D-alpha-tocopherol (1000 IU/day) (Eberlein-Konig et al 1998). The effect was seen after 8 days. The next to show reduction of the sunburn reaction was a 50-day study of 40 volunteers (20–47 years old), which showed that supplemental vitamin E (2 g/day) and C (3 g/day) protected against sunburn and resulted in increased vitamin E levels in keratinocytes (Fuchs & Kern 1998). This was once again confirmed in a controlled study of 45 healthy volunteers (Mireles-Rocha et al 2002). The doses used were lower in this study: 1200 IU/day of D-alpha-tocopherol in combination with vitamin C (2 g/day).

Scar tissue

Although vitamin E is widely used to diminish the appearance of scars, a small double-blind study of 15 patients who had undergone skin cancer removal found that applying an emollient preparation known

as Aquaphor with added vitamin E after surgery either had no effect or worsened the appearance of scars compared to Aquaphor alone (Baumann & Spencer 1999). A larger study of 80 people with hypertrophic scars and keloids found that treatment with vitamin E and silicone gel sheets was successful in scar treatment (Palmieri et al 1995). After 2 months, 95% of patients receiving vitamin E and gel sheet treatment had improved by 50%, whereas 75% had improved by 50% without vitamin E.

Type 1 diabetes

Although the Heart Outcomes Prevention Evaluation (HOPE) study involving 3654 people with diabetes failed to detect a preventative effect for long-term vitamin E (400 IU/day) on cardiovascular disease outcomes or nephropathy, other studies have identified that long-term treatment improves metabolic control in type 1 diabetes and may be useful to reduce oxidative stress (Jain et al 1996, Lonn et al 2002).

Chronic hepatitis C

According to a 2004 systematic review, significant improvements in biochemical responses were seen for vitamin E compared to a placebo (Coon & Ernst 2004). They report on one placebo-controlled trial in which a statistically significant reduction in liver enzyme (ALT) was observed during vitamin E treatment but reductions were not consistent for all patients and complete normalisation of ALT levels did not occur.

Asthma and atopy

Studies have consistently demonstrated beneficial associations between dietary vitamin E and ventilatory function, and a few have demonstrated beneficial associations with asthma and atopy (Devereux & Seaton 2005). However, benefits do not extend to vitamin E supplements, as a recent randomised study ($n = 72$) using natural vitamin E (500 mg/day) over 6 weeks found no clinical benefit in subjects with mild to moderate asthma (Pearson et al 2004).

Age-related macular degeneration (AMD)

According to a review of randomised trials comparing antioxidant vitamin and/or mineral supplement to controls, there is no evidence that antioxidant (vitamin E or beta-carotene) supplementation prevents AMD. However, there is evidence that supplementation with antioxidants (beta-carotene 15 mg, vitamin C 500 mg and vitamin E 400 IU) and zinc (elemental 80 mg) daily slows down the progression to advanced AMD and visual acuity loss in people with signs of the disease (Evans 2008). People with AMD, or early signs of the disease, may experience some benefit from taking supplements as used in the ARED trial (Sackett & Schenning 2002).

Huntington's disease

Vitamin E supplementation may slow the rate of motor decline early in the course of Huntington's disease, according to a randomised, double-blind, placebo-controlled study of high-dose D-alpha-tocopherol treatment (Peyser et al 1995). The study of 73 patients with Huntington's disease found that treatment with D-alpha-tocopherol had no effect on neurologic and neuropsychiatric symptoms in the treatment group overall; however, post hoc analysis revealed a significant selective therapeutic effect on neurologic symptoms for patients early in the course of the disorder.

OTHER USES

Oral supplements have been used to prevent or treat many other conditions such as exercise-induced tissue damage, some types of senile cataracts, epilepsy and fibromyalgia.

Vitamin E prophylaxis in premature babies significantly reduces the risk of stage 3+ retinopathy by 52%, according to a 1997 meta-analysis of six randomised studies (Raju et al 1997).

Infusions of vitamin E are being investigated as a means of preventing ischaemic reperfusion injury in liver and heart surgery (Bartels et al 2004, Jaxa-Chamiec et al 2005).

DOSAGE RANGE

The body's requirement for vitamin E changes according to the amount and type of fat eaten in the diet. For example, vitamin E requirements increase when there is a high intake of PUFAs (Wahlqvist 2002).

Many scientists believe it is difficult for an individual to consume more than 15 mg/day of alpha-tocopherol from food alone, without also increasing fat intake above recommended levels.

Recommendations for adults (Australian adequate intake)

- Men > 18 years: 10 mg/day alpha-tocopherol.
- Women > 18 years: 7 mg/day alpha-tocopherol.
- Upper level of intake: 300 mg/day alpha-tocopherol.
- Deficiency treatment: 800–1200 mg/day.

According to clinical studies

Both natural and synthetic forms of vitamin E have been evaluated in clinical trials at different doses and durations, and sometimes in combination with other nutrients that also exhibit antioxidant properties. Unless stated, dosages are for natural vitamin E (alpha-tocopherol).

- Alzheimer's disease: 2000 IU/day synthetic alpha-tocopherol.
- Anaemia in haemodialysis: 500 mg/day.
- Angina pectoris: 50–300 mg/day.
- Antioxidant effects: 400 IU/day.
- Cancer, to reduce cisplatin-induced neurotoxicity: oral vitamin E (600 mg/day) during chemotherapy and for 3 months after its cessation.
- Cerebral infarction prevention: 50 mg/day synthetic vitamin E.
- Colorectal cancer prevention: 50 mg/day long term.
- Cardiovascular disease primary prevention: 100–260 IU/day long term.
- Cardiovascular disease secondary prevention: 100–800 IU/day long term.

- Carotid atherosclerosis, slowing progression: 136 IU twice daily and vitamin C 250 mg (slow release) twice daily.
- Dementia prevention: 400 IU/day alpha-tocopherol plus vitamin C 500 mg/day.
- Haemodialysis, associated cramps: 400 mg/day alpha-tocopherol plus vitamin C 250 mg/day.
- Hypertension: 200 IU/day long term.
- Immune system support in the elderly: 200 mg/day.
- Intermittent claudication: 600–1600 IU/day.
- Ischaemic stroke prevention in high-risk hypertension: 50 mg/day.
- Male infertility: 200–800 mg/day.
- Menopausal symptoms: 800 IU/day.
- Nitrate tolerance prevention: 200 mg three times daily.
- Osteoarthritis: 1200 IU/day.
- Ovarian cancer: > 75 mg/day.
- Premenstrual symptoms: 400–600 IU/day.
- Prostate cancer prevention: 50 mg/day.
- Retinopathy of prematurity: 100 mg/kg/day.
- Rheumatoid arthritis: 1200 IU/day.
- Sunburn protection: 1000 IU/day up to 2000 mg/day plus vitamin C 2000–3000 mg/day.

TOXICITY

Vitamin E is relatively non-toxic. It is not stored as readily in the body as other fat-soluble vitamins and up to 60–70% of a daily dose is excreted in the faeces. Doses as high as 3200 mg/day have been used for 12 years with few adverse effects (Fariss & Zhang 2003).

In April 2000, the Food and Nutrition Board of the Institute of Medicine in the United States set an upper tolerable limit of 1500 IU of RRR-alpha-tocopherol as the highest dose unlikely to result in haemorrhage in most adults.

ADVERSE REACTIONS

Adverse effects are dose related and tend to occur only at very high supplemental doses (> 1200 IU/day); they include diarrhoea, flatulence, nausea and heart palpitations. Doses above this level should be used only under professional supervision.

SIGNIFICANT INTERACTIONS

Considering vitamin E is a fat-soluble vitamin, any medication that reduces the absorption of fats in the diet will also reduce the absorption of vitamin E. These include cholestyramine, colestipol, isoniazid, mineral oil, orlistat and sucralfate.

Chloroquine

According to in vitro research, vitamin E inhibits drug uptake in human cultured fibroblasts. The clinical significance of this observation is unknown. Observe patients taking this combination (Scuntaro et al 1996).

Chlorpromazine

According to in vitro research, vitamin E inhibits drug uptake in human cultured fibroblasts. The clinical significance of this observation is unknown — observe patients taking this combination (Scuntaro et al 1996).

Cisplatin

A review of four clinical trials testing the effects of the combination of vitamin E with cisplatin has shown that in all trials the incidence of chemotherapy–induced peripheral neuropathy was significantly reduced (Wolf et al 2008). Beneficial interaction, but should be used under professional supervision.

Warfarin

Contradictory results have been obtained in clinical studies that have investigated whether vitamin E affects platelet aggregation or coagulation. A dose of 1200 IU/day (800 mg of D-alpha-tocopherol) taken for 28 days had no effects on platelet aggregation or coagulation according to one clinical study (Morinobu et al 2002). Similarly, a second clinical study found that a lower dose of 600 mg (900 IU) of RRR-alpha-tocopherol taken daily for 12 weeks did not alter coagulation activity (Kitagawa & Mino 1989). In contrast, increased risk of gingival bleeding at doses of 50 mg/day was found by another study (Liede et al 1998).

Overall, it appears that people with reduced levels of vitamin K may be more susceptible to the effects of vitamin E, potentiating warfarin activity. Until further research can clarify whether the interaction is clinically significant for most people, it is recommended that prothrombin time ratio, or INR, should be closely monitored upon the addition and withdrawal of treatment with high-dose vitamin E supplements.

Doxorubicin

One study found that oral DL-alpha-tocopheryl acetate (1600 IU/day) prevented doxorubicin-induced alopecia (Wood 1985). The same dose of oral DL-alpha-tocopheryl acetate failed to prevent alopecia after doxorubicin treatment following mastectomy for breast cancer (Martin-Jimenez et al 1986). It also failed to prevent alopecia in a second study of 20 patients with different types of solid tumours (Perez et al 1986). Possible beneficial interaction but difficult to assess.

Nitrates

Oral vitamin E prevented nitrate tolerance when given concurrently with transdermal nitroglycerin (10 mg/24 hours), according to one randomised placebo-controlled study (Watanabe et al 1997). Beneficial interaction possible.

NSAIDs and simple analgesics

Vitamin E may enhance the pain-modifying activity of drugs. Beneficial interaction possible; drug dosage may require modification.

Propranolol

According to in vitro research, vitamin E inhibits drug uptake in human cultured fibroblasts. The clinical significance of this observation is unknown. Observe patients taking this combination (Scuntaro et al 1996).

PRACTICE POINTS/PATIENT COUNSELLING

- Vitamin E is actually a generic term used to describe any chemical entity that displays the biological activity of RRR-alpha-tocopherol, the most abundant form found in nature. The 'natural' form is the most potent of all eight forms of vitamin E, although there is evidence that other tocopherols also exhibit significant beneficial effects.
- It is involved in myriad biochemical processes such as immunocompetence and neurological function, but its most important biological function is that of an antioxidant.
- Vitamin E is used for many different indications. There is evidence to suggest that supplementation may be useful in:
  - secondary cardiovascular disease prevention, although effects are inconsistent
  - slowing down progression of Alzheimer's dementia, although effects are inconsistent
  - enhancing immune function in the elderly
  - preventing anaemia and treating cramps in patients on haemodialysis
  - reducing PMS, dysmenorrhoea and menopause symptoms
  - reducing pain in OA and RA
  - improving some forms of male infertility
  - reducing risk of stage 3+ retinopathy in premature babies
  - preventing ischaemic stroke in high-risk hypertensive patients
  - reducing incidence of some cancers, although effects are inconsistent
  - preventing sunburn (when used with vitamin C)
  - slowing down carotid atherosclerosis (when used with vitamin C)
  - reducing blood pressure
  - reducing nitrate tolerance
  - reducing cisplatin-induced neurotoxicity.
- Oral supplements have been used to prevent or treat many other conditions, such as exerciser-induced tissue damage, some types of senile cataracts, epilepsy and fibromyalgia.
- It is a popular ingredient in many moisturising preparations used to: alleviate dry and cracked skin; assist in the repair of abrasions, burns, grazes and skin lesions; prevent stretch marks; and diminish scar tissue. Vitamin E oil is used as a stand-alone preparation or incorporated into a cream or ointment base for these purposes.
- People with impaired coagulation, inherited bleeding disorders, a history of haemorrhagic stroke or vitamin K deficiency, or who are at risk of pulmonary embolism or thrombophlebitis should use high-dose supplements under medical supervision.

CONTRAINDICATIONS AND PRECAUTIONS

Vitamin E is considered to be a safe substance.

People with impaired coagulation, inherited bleeding disorders, a history of haemorrhagic stroke, vitamin K deficiency or at risk of pulmonary embolism or thrombophlebitis should use high-dose supplements under medical supervision.

Although it was thought that people with hypertension wanting to take supplements should start with low doses, evidence does not support the concern that high-dose supplements will significantly elevate blood pressure. Suspend use of high doses (> 1000 IU/day) 1 week before major surgery.

PREGNANCY USE

Vitamin E is considered to be safe in pregnancy.

PATIENTS' FAQs

What will this vitamin do for me?

Vitamin E is essential for health and wellbeing. It is involved in many important biological processes in the body and may prevent serious diseases such as heart disease and some cancers; however, people with these conditions should seek professional advice. It is also used to reduce symptoms in common conditions such as arthritis, PMS and menopause. Vitamin E supplements enhance immune function in the elderly and may slow the progression of Alzheimer's dementia, although this is still not conclusive. Oral supplements have been used to prevent or treat many other conditions such as exercise-induced tissue damage, some types of senile cataracts, epilepsy and fibromyalgia.

When will it start to work?

This depends largely on the reason for taking the supplement. In the case of disease prevention, studies suggest that long-term use is necessary (i.e. 2–3 years or longer). When using vitamin E to reduce symptoms, effects have generally been seen within 3 months.

Are there any safety issues?

People with impaired coagulation, inherited bleeding disorders, a history of haemorrhagic stroke or vitamin K deficiency, or who are at risk of pulmonary embolism or thrombophlebitis should use high-dose supplements under medical supervision. Additionally, vitamin E can interact with some medicines, so professional advice is recommended when using high-dose supplements.

Wild yam

HISTORICAL NOTE Wild yams have made a significant contribution as a root crop to tribal people in some parts of the world, such as Nepal. They are usually consumed boiled, steamed, baked or fried. Many different forms and cultivars of the wild edible yam species are available in different areas, and it is likely that these differ in composition and nutritional values. Traditionally, wild yams have also been used as medicine and are believed to exert antispasmodic, anti-inflammatory and autonomic nervous system relaxant effects. Wild yam is a source of diosgenin, the raw material originally used to produce progesterone in the laboratory.

COMMON NAME
Wild yam

OTHER NAMES
Atlantic yam, barbasco, China root, colic root, devil's bones, Mexican yam, natural DHEA, rheumatism root, wild Mexican yam, yuma

BOTANICAL NAME/FAMILY
Discorea composita, *D. floribunda*, *D. mexicana*, *D. macrostachya*, *D. villosa* (family Dioscoreaceae [yams])

PLANT PART USED
Root and rhizome

CHEMICAL COMPONENTS
The root of the wild yam contains diosgenin, dioscin, dioscorin and a range of vitamins and minerals such as vitamin C, beta-carotene, vitamins B_1, B_2 and B_3, iron, magnesium, potassium, selenium and zinc (USDA 2003), along with polyphenols (Bhandari & Kawabata 2004). Although diosgenin can be converted to dihydroepiandosterone (DHEA) and other steroid compounds in the laboratory, and has been used for commercial production of these compounds, this conversion does not occur in the human body. Additionally, wild yam does not contain progesterone or any other active steroid hormones.

MAIN ACTIONS

Hormonal actions
The evidence of a hormonal action with wild yam varies. Wild yam extract may enhance oestradiol binding to oestrogen receptors and induce transcription activity in oestrogen-responsive cells (see wild yam at http://www.naturaldatabase.com), and diosgenin has been observed to have an oestrogenic action on mouse mammary epithelium (Aradhana & Kale 1992). In contrast, in an oestrogen competition assay using human breast cancer cell, diosgenin was found to cause an acute, endothelium-independent coronary artery relaxation, but did not interact with oestrogen or progesterone receptors (Au et al 2004), and extracts with an upper limit of 3.5% diosgenin have been found to have no oestrogenic activity (Hooker 2004).

One study looking at steroid-hormone-regulated gene expression using an in vitro tissue-culture indicator system suggests that wild yam extract does not have significant oestrogenic or progesteronal activity, but rather weak anti-oestrogenic and/or anti-androgenic activities (Rosenberg Zand et al 2001). A further study suggests that wild yam extract suppresses progesterone synthesis without direct effects on oestrogen or progesterone receptors (Zava et al 1998). In an in vivo study, supplementation with diosgenin protected the kidney from morphological changes associated with ovariectomy (Tucci & Benghuzzi 2003) and produced a significant decrease in the cortical and medullary adrenal areas of ovariectomised rats (Benghuzzi et al 2003).

There is in vitro evidence that diosgenin upregulates vascular endothelial growth factor-A and promotes angiogenesis in pre-osteoblast-like cells via pathways involving oestrogen receptors (Men et al 2005).

Cholagogue
There appears to be more consistent evidence for wild yam's effect on bile flow. Diosgenin has been shown to increase biliary secretion of cholesterol (Accatino et al 1998, Yamada et al 1997) and prevent oestrogen-induced bile flow suppression in rats (Accatino et al 1998), as well as increase elimination of indomethacin and reduce indomethacin-induced intestinal inflammation (Yamada et al 1997).

OTHER ACTIONS
Traditionally, wild yam is also believed to exert antispasmodic, anti-inflammatory and autonomic nervous system relaxant effects (Fisher & Painter 1996). Wild yam exhibits significant antioxidant activity (Bhandari & Kawabata 2004).

Clinical note — The major influence of wild yam on modern medicine

The Mexican wild yam has had a major influence on drug development and modern medical practice, although few people are familiar with the story and misunderstandings abound.

In the late 1930s scientists entering the field of sex endocrinology were confronted with the sober reality that they were dealing with research materials (animal glands) that needed to be sourced from slaughterhouses and were not readily available in sufficient quantities (Soto Laveaga 2005). Eventually, female urine was identified as a better source of hormones and provided an alternative. As pharmaceutical companies embarked upon large-scale hormone production, it became apparent that a cheaper and more abundant source of raw materials would need to be found; hence, a search through the plant kingdom ensued.

The American chemist Russell Marker identified that saponins in plants could be chemically modified to produce steroids and that sex hormones could be synthesised using yams (Soto Laveaga 2005). For several years he tried unsuccessfully to direct pharmaceutical companies to use Mexico as a source of wild yams, but the general perception was that Mexico was too politically unstable and unsophisticated. Over time, changes in the infrastructure of the Mexican countryside coincided with further chemical discoveries, and wild yam root picking became a financial panacea to previously unemployed peasants in yam-rich areas. By the 1950s, scientists at the pharmaceutical company Upjohn had found a way to convert diosgenin to progesterone, then to hydrocortisone and finally cortisone, thereby reinforcing the importance of wild yam as a source of raw materials for steroid drugs. Considering the importance of these events, it could be said that wild yams revolutionised the world of modern medicine.

At one stage Mexican wild yams provided up to 90% of the world's raw material for steroid drug synthesis, but this has steadily fallen owing to the rapid increase in demand for larger quantities and Mexico's reduced ability to produce wild yam tubers (Soto Laveaga 2005).

CLINICAL USE

The therapeutic effectiveness of wild yam has not been significantly investigated under clinical trial conditions, so evidence is derived from traditional, in vitro and animal studies.

Menopausal symptoms and other female reproductive conditions

Although wild yam is a popular treatment for menopausal symptoms, there is currently no clinical research supporting its use for these indications.

Wild yam has been used as a 'natural alternative' to oestrogen replacement therapy, to treat postmenopausal vaginal dryness, PMS and osteoporosis, and to increase energy and libido in men and women, as well as for breast enlargement. The use of wild yam as a natural progesterone appears misguided, because diosgenin is not converted to progesterone, DHEA or other steroid hormones in vivo. One small, double-blind, placebo-controlled crossover trial of topical wild yam extract showed no effect on menopausal symptoms (Komesaroff et al 2001). The study involved 23 healthy women suffering from troublesome menopause symptoms. After a 4-week baseline period, each woman was randomly assigned the active cream and matching placebo for 3 months. No changes in body weight, SBP or DBP, levels of total serum cholesterol, triglyceride, HDL-cholesterol, FSH, glucose, oestradiol, or serum or salivary progesterone were detected after 3 months' treatment.

OTHER USES

Wild yam has been used traditionally as an antispasmodic for treating diverticulosis, gall bladder colic, painful menstruation, cramp, nausea in pregnancy and rheumatoid arthritis, and for increasing energy (Fisher & Painter 1996). It may also be useful when combined with other herbs for irritable bowel syndrome (Abascal & Yarnell 2005).

DOSAGE RANGE

- Decoction of dried root: 2–4 g three times daily.
- Tincture (1:5): 2–10 mL three times daily.
- Liquid extract (1:2): 3–6 mL/day.

TOXICITY

Considering that wild yams are widely consumed as food by several tribal groups, it appears that dietary ingestion is non-toxic. After assessment with short-term toxicity tests, dermal irritation tests, a sensitisation test, an ocular irritation test, a rat uterotropic assay and genotoxicity tests, wild yam was deemed safe for use in cosmetic products (Hooker 2004).

ADVERSE REACTIONS

In large doses, wild yam may cause nausea, vomiting and diarrhoea.

SIGNIFICANT INTERACTIONS

Insufficient reliable data are available to determine whether interactions may occur.

CONTRAINDICATIONS AND PRECAUTIONS

None known.

PREGNANCY USE

Likely to be safe when consumed in dietary amounts; however, safety is not known when used in larger quantities.

PATIENTS' FAQs

What will this herb do for me?

Although the herb is used medicinally to treat menopausal symptoms, there is no scientific evidence to support this.

When will it start to work?

This cannot be answered based on scientific evidence.

Are there any safety issues?
Given that it is consumed as food, usual dietary intakes may be considered safe.

PRACTICE POINTS/PATIENT COUNSELLING
- Wild yam is a popular root vegetable in some parts of the world.
- It is also a popular ingredient in commercial herbal formulas developed for menopausal women.
- Wild yam has been touted as having progesteronal and/or oestrogenic activity, but current evidence suggests this is unlikely.
- There is no clinical or scientific evidence to support the use of wild yam in the treatment of conditions of the female reproductive system.
- Wild yam root may be useful as an antispasmodic. Its use as a source of naturally occurring sex hormones appears misguided.

Willowbark

HISTORICAL NOTE This herb has been used as a therapeutic agent since ancient times, with some reports of its use around 500 BC in ancient China as a treatment for pain and fever, and around 400 BC by Hippocrates, who recommended the bark be chewed for relief of fever and pain. As centuries passed, herbalists continued to prescribe the bark for many conditions, and by the 18th century it was widely used as an antipyretic and analgesic. During the late 1820s, French and German scientists extracted the glycosidic constituents, including salicin (Hedner & Everts 1998). The oxidation of salicin yields salicylic acid, which was produced in the mid 1800s but had limited clinical use due to the gastric irritation it caused. In 1853 a French chemist neutralised salicylic acid to create acetylsalicylic acid, but had no interest in marketing it and abandoned his discovery. A Bayer chemist called Hoffmann rediscovered acetylsalicylic acid in 1897 as a better tolerated treatment for his father's rheumatoid arthritis and within 2 years it was marketed by Bayer under the tradename of Aspirin (Setty & Sigal 2005). Since then it has become one of the most successful medicines in history. Although many believe aspirin was synthesised from the salicin found in willowbark, it was actually the salicin found in another herb, meadowsweet, from which aspirin was developed.

OTHER NAMES

White willowbark, brittle willow, bay willow, crack willow, purple willow, silberweide, violet willow

While white willow (*Salix alba*) is the willow species most commonly used for medicinal purposes, crack willow (*S. fragilis*), purple willow (*S. purpurea*) and violet willow (*S. daphnoides*) are all salicin-rich and are sometimes sold under the label of willow bark (Setty & Sigal 2005).

BOTANICAL NAME/FAMILY

Salix alba (family Salicaceae)

PLANT PART USED

Bark

CHEMICAL COMPONENTS

Phenolic glycosides (mainly salicylates including salicin and its derivatives), tannins (mainly catechin tannins, some gallontannins and condensed tannins [procyanidins]), lignans and flavonoids.

MAIN ACTIONS

Anti-inflammatory and analgesic

Clinical studies using willowbark preparations standardised to salicin content have shown anti-inflammatory and analgesic activity (Chrubasik et al 2000, 2001a, 2001b, Mills et al 1996, Schmid et al 2000). In vitro studies have demonstrated that *Salix* extract inhibits COX-2-mediated PGE_2 release and that it is a weak inhibitor of pro-inflammatory cytokines (Fiebich & Chrubasik 2004). While salicin is considered the main analgesic constituent, it is now thought that other constituents such as tannins, flavonoids and salicin esters may contribute to its overall effect (Schmid et al 2001).

CLINICAL USE

In clinical practice, willowbark is generally used as a symptomatic treatment in osteoarthritic conditions and lower back pain. Of the five RCTs conducted to investigate its effects in these conditions, all but one have produced positive results (Biegert et al 2004, Chrubasik et al 2000, 2001a, Mills et al 1996, Schmid et al 2000).

Joint pain and inflammation

Osteoarthritis

Four randomised double-blind trials have investigated the efficacy of willowbark in people with osteoarthritis, with the two earlier studies finding that herbal treatment produced symptom-relieving effects superior to a placebo (Biegert et al 2004, Mills et al 1996, Schmid et al 2000). Seventy-eight subjects were randomly assigned willowbark extract (240 mg salicin/day) or a placebo over a 2-week period, after which active treatment was found to produce a statistically significant improvement (Schmid et al 2000). Mills et al (1996), testing willowbark in 82 patients with chronic arthritic pain, also found active treatment produced a statistically significant alleviation of pain symptoms. The effectiveness and tolerance of willowbark extract compared to conventional therapies was tested in patients with knee or hip pain in a cohort study with a control group. This open, observational study included 90 patients treated with a standardised willowbark extract preparation (equivalent to 240 mg salicin daily), and a reference group of 41 patients with a standard therapy prescribed by a doctor and 8 patients with a combination of the two. Both the doctors and the patients judged the effectiveness in both groups to be comparable. After 6 weeks, the effectiveness and tolerance of the willowbark extract was better than conventional therapy. No adverse events were recorded in the willowbark group (Beer & Wegener 2008).

These findings contrast with earlier studies in which willowbark failed to reduce Western Ontario and McMaster Universities Arthritis Index (WOMAC) pain scores better than a placebo in a trial on 127 outpatients with painful hip or knee osteoarthritis (Biegert et al 2004). Patients were randomised to receive willow bark extract, corresponding to 240 mg of salicin/day, diclofenac 100 mg/day, or a placebo. Treatment with diclofenac produced the strongest pain-reducing effects (WOMAC scores decreased by 47%) compared with willowbark (17% reduction) and the placebo (10% reduction), with the difference between willow bark extract and placebo not statistically significant.

> ***Clinical note — Lack of significant haemotological effects***
>
> It has largely been assumed that willowbark alters platelet aggregation and increases bleeding time, in much the same way as aspirin. Whether this is in fact correct and clinically significant has been investigated by Krivoy et al (2001). The clinical study found that consumption of *Salicis cortex* extract (containing 240 mg salicin per daily dose) only minimally affected platelet aggregation compared to a cardioprotective dose of acetylsalicylate (up to 100 mg/day). The particular preparation studied produced a total serum salicylate concentration bioequivalent to only 50 mg acetylsalicylate.

Rheumatoid arthritis (RA)

Willowbark extract (corresponding to 240 mg salicin/day) failed to significantly reduce pain in people with active RA, according to a small, double-blind, randomised study of 26 volunteers (Biegert et al 2004). The main outcome measure used was each patient's assessment of pain rated on a 100 mm visual analogue scale.

Lower back pain

Two randomised studies have investigated the use of oral white willowbark in people with acute episodes of chronic non-specific low-back pain (Chrubasik 2000, 2001a). According to a 2006 Cochrane systematic review, there is moderate evidence that a daily dose of 240 mg salicin from an extract of *S. alba* reduces pain more than either a placebo or a daily dose of 120 mg of salicin in the short term for individuals with acute episodes of chronic non-specific low-back pain (Gagnier et al 2006).

One randomised, placebo-controlled study involving 210 patients with chronic lower back pain found that 39% of those treated with 240 mg salicin became pain-free after 4 weeks compared with 6% in the placebo group. This response was achieved after 1 week (Chrubasik et al 2000). Similar results were achieved in an open trial conducted over 18 months that compared willowbark extract containing 120 mg of salicin or 240 mg salicin with what the authors term 'conventional treatment' in 451 people with acute exacerbations of lower back pain. Those receiving 240 mg salicin experienced the best results, with 40% becoming pain-free after 4 weeks, compared to 19% in the 120 mg salicin group and 18% in the control group (Chrubasik et al 2001b).

Comparative trial with rofecoxib

No significant differences in pain-relieving effects were found between white willowbark, standardised to provide a daily dose of 240 mg salicin,

and 12.5 mg of the synthetic COX-2 inhibitor rofecoxib according to a randomised trial of individuals with acute episodes of chronic non-specific low-back pain (Chrubasik et al 2001a). With regard to rescue treatments, the percentage of patients requiring NSAIDs, tramadol or both was 10% for the willowbark group and 13% for the rofecoxib group. Approximately 90% of physicians and patients rated either treatment as effective and close to 100% rated either treatment as acceptable.

Given that some pharmaceutical treatments used in the management of pain and inflammatory conditions are costly, such as the newer COX-2 inhibitors, Chrubasik et al (2001b) also compared the cost savings associated with the use of willowbark. A dose of 120 mg salicin/day from willowbark reduced overall patient spending on additional drugs by about 35–50%. In comparison, 240 mg salicin/day produced superior pain relief that resulted in even less reliance on supplementary treatments, but savings were outweighed by the extra cost of the higher dose.

In 2007 a systematic review of the same studies, Gagnier et al concluded there is moderate-level evidence to support the acute and short-term use of willowbark for pain at daily doses standardised to 120 mg or 240 mg salicin, where it has relative equivalence to 12.5 mg per day of rofecoxib (Gagnier et al 2007).

Fever and headaches

The known activity of salicylate constituents in the herb provide support for its use as symptomatic treatment in fever and headaches. Commission E has approved willowbark for these indications (Blumenthal et al 2000). Despite this, only one clinical study has been conducted exploring the effectiveness of willowbark for headaches, but it was used in combination with the herb feverfew, so the efficacy of stand-alone treatment remains unknown (Shrivastava et al 2006).

In combination

A prospective, open-label study was performed in 12 patients diagnosed with migraine without aura. Twelve weeks' treatment with feverfew *(Tanacetum parthenium*, 300 mg) plus willowbark (300 mg) twice daily was shown to reduce attack frequency and intensity, with 70% patients having a reduction of at least 50%. Attack duration also decreased significantly in all patients. Self-assessed general health, physical performance, memory and anxiety also improved by the end of the study. The treatment was well tolerated and no adverse events occurred (Shrivastava et al 2006).

OTHER USES

A recent in vitro study that examined the effects of the main groups of compounds (salicylalcohol derivates, flavonoids, proanthocyanidins) and salicin isolated from willowbark extract BNO 1455 found that all compounds exerted antiproliferative activity, inhibited the cell growth and promoted apoptosis in human colon and lung cancer cell lines, irrespective of their COX-selectivity (Hostanska et al 2007)

DOSAGE RANGE

- Tincture (1:1): 1–2 mL three times daily.
- Decoction: 1–3 g finely chopped herb in 1 cup of cold water, brought to the boil then reduced to simmer for 5 minutes, drunk 3–4 times daily.

According to clinical studies

- Osteoarthritic joint pain and inflammation — willowbark preparations standardised to total salicin content and providing 240 mg daily in divided doses.
- Acute episodes of chronic non-specific low-back pain — willowbark preparations standardised to total salicin content and providing 240 mg daily in divided doses.

ADVERSE REACTIONS

None reported. Theoretically, the tannin and salicylate content may cause gastrointestinal disturbances.

SIGNIFICANT INTERACTIONS

Controlled studies are not available, therefore interactions are based on evidence of pharmacological activity and clinical significance is uncertain.

Anticoagulants

Although a clinical study found that consumption of salicin 240 mg/day produced minimal effects on platelet aggregation, higher doses may have a significant effect. Exercise caution with high doses > 240 mg salicin/day.

Salicylate drugs

Theoretically, concurrent use may result in additive effects, although this has yet to be tested. Observe patients taking this combination.

Aspirin

Theoretically, willowbark may enhance the anti-inflammatory and antiplatelet effects at doses of salicin 240 mg/day. Observe patients taking this combination; beneficial interaction may be possible.

An increased risk of bleeding is theoretically possible with high doses > 240 mg salicin. Observe.

NSAIDs

A reduction in drug requirements may be possible with the use of white willowbark for lower back pain according to a randomised study. Beneficial interaction is possible.

CONTRAINDICATIONS AND PRECAUTIONS

Commission E states that there is no evidence that willowbark preparations should be contraindicated in small children because of the risk of Reye's syndrome, as the salicylates in the herb are metabolised differently from those in aspirin.

Owing to the relatively high concentration of salicylates in this herb, it should not be used by people with salicylate sensitivity.

PREGNANCY USE

It is generally not advised to recommend salicylate-containing medicines during pregnancy or lactation, although no restrictions are known for willowbark directly.

PRACTICE POINTS/PATIENT COUNSELLING

- Evidence from several RCTs suggests that willowbark is an effective treatment for relieving pain in chronic backache and osteoarthritis.
- The results of one clinical study suggest it is as effective as 12.5 mg of the synthetic COX-2 inhibitor rofecoxib when used at a daily dose of 240 mg salicin.
- People using willowbark may find they have lowered requirements for traditional anti-inflammatory medicines such as NSAIDs.
- Currently, there is no evidence to suggest gastrointestinal side effects or significant platelet inhibition.
- Due to its salicylate content, people with salicylate sensitivity should avoid use of willowbark.

PATIENTS' FAQs

What will this herb do for me?

Scientific studies have found that willowbark is a useful treatment for relieving pain in osteoarthritis and chronic backache. It may also relieve symptoms of headache and fever.

When will it start to work?

Studies using willowbark preparations in diseases characterised by joint pain have found that effects start within 1 week of use.

Are there any safety issues?

Willowbark appears to be free of major side effects or drug interactions, but it should not be taken by people with salicylate sensitivity.

Withania

HISTORICAL NOTE The name ashwagandha (one of the common names for this herb) comes from the sanskrit meaning 'horse-like smell'. Apparently, this name not only refers to the smell of the herb but also to its strengthening and aphrodisiac qualities. It is often referred to as 'Indian ginseng' because it is used in much the same way as *Panax ginseng* in TCM, although it is considered less stimulating. In Ayurvedic medicine it is classified as a 'rasayana', used to promote physical and mental health and improve vitality and longevity (Kulkarni & Dhir 2008).

OTHER NAMES

Ashwagandha (and a variety of spellings including ashvagandha, ashwaganda, asvagandha), Ayurvedic ginseng, Indian ginseng, winter cherry

BOTANICAL NAME/FAMILY

Withania somnifera (family Solanaceae)

Sometimes confused with *Physalis alkekengi*, also known as winter cherry.

PLANT PARTS USED

Primarily root, although berry, leaves and bark are sometimes used.

CHEMICAL COMPONENTS

Steroidal lactones (withanolides, withaferin A), alkaloids (including withanine, somniferine, isopelletierine, anaferine, tropine, pseudotropine), flavonoids, saponins, sitoindosides, iron, choline, acylsteryl glucosides, coumarins (scopoletin and aesculetin), triterpene (beta-amyrin), phytosterols (stigmasterol, stigmasterol glucoside, beta-sitosterol and beta-sitosterol glucoside), Viscosa lactone B, alpha+beta glucose, essential oils (ipuranol, withaniol) (Misra et al 2008, Abou-Douh 2002, Kulkarni & Verma 1993, Mills & Bone 2000).

Plants sourced from Sardinia, Italy have significantly higher levels of withaferin A content than those sourced from India or Sicily (Scartezzini et al 2007).

MAIN ACTIONS

Withania and several of its key constituents have been subjected to scientific investigation in vitro and in vivo. Whilst the pharmacological actions of individual components is important to understand, clinical effects are difficult to predict from these studies as the ultimate effect of the herbal treatment will be a result of many intraherbal interactions.

Adaptogen (modulates stress responses)

Withania has been shown to attenuate the negative effects of chronic stress in rats, including hyperglycaemia, glucose intolerance, increase in plasma corticosteroid levels, gastric ulcerations, male sexual dysfunction, cognitive deficits, immunosuppression and mental depression (Bhattacharya & Muruganandam 2003).

Animal trials have shown that a withanolide-free hydrosoluble fraction of withania reduces the stress response induced both chemically and physically (Singh et al 2003). It suppresses stress-induced increases in dopamine receptors in the corpus striatum and acts as a GABA-mimetic agent by binding to GABA receptors (Mehta et al 1991, Upton 2000). Animal studies also suggest an ability to reduce adrenal weight and plasma cortisol levels (Kurandikar et al 1986), thus potentially protecting against the negative effects of elevated cortisol levels in chronic stress and allostasis.

Nervous system activity

Cognitive enhancement

The potent acetylcholinesterase inhibitory activity of withania in vitro may help to explain its traditional use for improving cognition (Vinutha et al 2007). Memory enhancement has been confirmed by animal studies and appears to be mediated by a cholinergic effect (Dhuley 2001). Increased cortical muscarinic acetylcholine receptor capacity has been observed in animals and humans with extracts of withania (Schliebs et al 1997). Several withanolides exert calcium antagonistic ability, together with anticholinesterase activity, by inhibiting butyrylcholinesterase and acetylcholinesterase enzymes (Choudhary MI et al 2004, 2005). The presence of choline in the herb may also contribute to the production of acetylcholine and further increase cholinergic effects.

Neuroprotective

Several animal studies indicate the potential for protection of neurons (Jain et al 2001), including protection from neuronal injury in Parkinson's disease (Ahmad et al 2005) and promotion of dendrite formation (Tohda et al 2000). One possible explanation is due to the antioxidant properties of withania (Parihar & Hemnani 2003).

In animal experiments withania has been shown to be useful for the treatment of drug-induced dyskinesia (chewing movements, tongue protrusion and buccal tremors) due to reserpine (an antihypertensive and antipsychotic agent no longer available in Australia) and haloperidol (an antipsychotic). In one study, *W. somnifera* root extract (50 and 100 mg/kg) was administered for 4 weeks and dose-dependently reduced reserpine-induced vacuous chewing movements and tongue protrusions, and memory retention deficits in rats. The effect was most likely due to reversal of the drug-induced depletion of glutathione (GSH), superoxide dismutase (SOD) and catalase (Naidu et al 2006). Other researchers support the theory that benefits of withania appear to be due to its antioxidant rather than GABA-mimetic action (Bhattacharya SK et al 2002, Naidu et al 2003).

In vitro results suggest that withanolide A, withanoside IV and withanoside VI are involved in reconstructing neuronal networks, including axons, dendrites, pre- and postsynapses in the neurons (Tohda 2008, Kuboyama et al 2002, 2005). In vivo, oral withanolide A, withanoside IV and withanoside VI (10 μmol/kg/day for 12 days) have been shown to improve experimentally-induced memory impairment, neurite atrophy and synaptic loss in the cerebral cortex and hippocampus in mice; and withanoside IV (10 μmol/kg/day for 21 days) improves locomotor functions in mice with spinal cord injury (SCI) (Tohda 2008).

Antioxidant

Withania exerts an indirect antioxidant action in vivo (Bhattacharya SK et al 1997, Bhattacharya A et al 2001). Daily administration of *W. somnifera* root extract increases hepatic glucose-6-phosphatase activity and decreases hepatic lipid peroxidation, most likely by increasing the activity of endogenous antioxidant enzymes (Panda & Kar 1997, 1998, 1999). In vitro *W. somnifera* inhibits both the lipid peroxidation and the protein oxidative modification induced by copper (Gupta et al 2003). In animal studies the antioxidant actions have been proposed as a possible mechanism for withania, preventing the negative effects of stroke induced by middle cerebral artery occlusion in rats (Choudhary G et al 2003). The antioxidant properties may also contribute to the anticataleptic effect noted in studies of haloperidol-induced catalepsy in albino mice (Nair et al 2008).

Increases haematopoiesis

Animal trials indicate the herb increases haemoglobin and red blood cell levels (Ziauddin et al 1996) and increases haematopoiesis (Aphale et al 1998). The iron content of the herb may further contribute to its role in red blood cell formation.

Immunomodulation

Immunomodulating activity has been demonstrated in vivo for withania, including an increase in white blood cell, platelet and neutrophil counts (Agarwal et al 1999, Davis & Kuttan 2000, Gupta YK et al 2001, Ziauddin et al 1996), proliferation of lymphocytes, increased INF-gamma (Teixeira et al 2006) and IL-2 levels and a reduction in TNF (Davis & Kuttan 1999). In vitro, increased nitric

oxide production by macrophages has also been reported (Iuvone et al 2003). Withaferin A and withanolide D may cause immunosuppression, but other factors have immunostimulant effects (NMCD 2005).

In animal studies, oral administration of a standardised fluid extract (1:1) of withania (30 mg/kg) for 15 days resulted in enhanced Th1 immunity (increased expression of T helper cell (Th1) cytokines, interferon (IFN)-gamma and interleukin (IL)-2) with a moderate decline in Th2 (decreased expression of Th2 cytokine IL-4). This effect appeared to be due to withanolide A. The extract also strongly activated macrophage function and no toxicity was noted (Malik et al 2007). Other studies have confirmed an increased expression of Th1 cytokines in chronically stressed (Khan et al 2006) and immunosuppressed mice (Bani et al 2006). Although human trials are required to confirm these effects, withania shows promise for selective Th1/Th2 modulation.

Antibacterial and antifungal activity

Animal and in vitro studies have shown antibacterial effects against *Staphylococcus aureus*, *Listeria monocytogenes*, *Bacillus anthracis*, *Bacillus subtilis*, *Salmonella enteridis* (Akin et al 1986) and *Salmonella typhimurium* (Owais et al 2005). The methanol and hexane extracts of both the leaves and the roots have potent antibacterial activity against *S. typhimurium* and *Escherichia coli* (Arora et al 2004); and the steroidal withanolides from the related species *W. coagulens* have been found to have antifungal activity against *Allescheria boydii*, *Aspergillus niger*, *Curvularia lunata*, *Drechslera rostrata*, *Epidermophyton floccosum*, *Microsporum canis*, *Nigrospora oryzae*, *Pleurotus ostreatus* and *Stachybotrys atra* (Choudhary et al 1995). *W. somnifera* glycoprotein exerts an antibacterial activity against *Clavibacter michiganensis* and a fungistastic effect against *Aspergillus flavus, Fusarium oxysporum* and *F. verticilloides* (by inhibiting spore germination and hyphal growth) (Girish et al 2006).

Anti-inflammatory activity

Withania extract suppresses the production of pro-inflammatory molecules in vitro. This is partly due to inhibition of transcription factors NF-kappaB and AP-1 by withanolides (steroidal lactones) (Ichikawa et al 2006, Kaileh et al 2007, Singh et al 2007). Several withanolides exert selective COX-2 enzyme inhibition (Jayaprakasam & Nair 2003) and withania has been found to decrease alpha-2-macroglobulin, a liver-synthesised plasma protein that increases during inflammation (Anbalagan & Sadique 1985). A reduction in the erythrocyte sedimentation rate has also been noted in a double-blind clinical trial of 50–59 year old males (Kupparajan et al 1980).

Chondroprotective

Withania root powder has demonstrated chondroprotective effects in vitro (human osteoarthritic cartilage matrix) inhibiting the gelatinase activity of collagenase type 2 enzyme and exerting a significant short-term chondroprotective effect in a subset (50%) of patient samples (Sumantran et al 2007). In vivo the root powder rectified biochemical changes resulting from experimentally-induced arthritis in rats (Rasool & Varalakshmi 2007). Associated with arthritis were increased levels of lipid peroxides, glycoproteins and urinary constituents; and depletion of antioxidant status and bone collagen. These biochemical alterations were ameliorated significantly by oral administration of *W. somnifera* root powder (1000 mg/kg body weight) in test animals. It should be noted however that the high dose used (1000 mg/kg bodyweight) is not likely to be reproducible in human trials.

Anticancer (antineoplastic and chemoprevention)

In vitro studies have determined that withania extracts possess cell-cycle disruption and anti-angiogenic activity (Mathur et al 2006). Withania stimulates the production of cytotoxic T-lymphocytes in vivo and in vitro, and may prevent or reduce tumour growth (Davis & Kuttan 2002, Jayaprakasam et al 2003). In animal models, withania was found to prevent skin carcinoma induced by UVB radiation (Mathur et al 2004) and forestomach tumours (Padmavathi et al 2005); reduce the incidence, number and size of tumours; and to counteract the associated decrease in body weight (Singh et al 1986).

The withaferin A fraction appears to exert anti-angiogenic activity (Mohan et al 2004), antigenotoxic effects on bone marrow (Panjamurthy et al 2008), and may be partly responsible for the antineoplastic effects observed in both in vitro and in vivo studies (Uma Devi 1995, 1996). The antioxidant effects aid in the prevention of DNA damage by mutagens (Khanam & Devi 2005) and this in combination with detoxifying properties, anti-inflammatory and immunomodulatory effects, determined in animal studies, are likely to contribute to its chemopreventive action (Prakash et al 2001, 2002).

Because several genes that regulate cellular proliferation, carcinogenesis, metastasis and inflammation are regulated by nuclear factor-kappaB (NF-kappaB), the ability of withanolides to inhibit activation of NF-kappaB and NF-kappaB-regulated gene expression may partly explain the role of withania in enhancing apoptosis and inhibiting invasion and osteoclastogenesis (Ichikawa et al 2006).

Anxiolytic and antidepressant

Animal studies have found glycowithanolides exert anxiolytic effects comparable to those of lorazepam, and antidepressant effects comparable to those of the antidepressant drug imipramine (Bhattacharya SK et al 2000).

Anxiolytic and antidepressant activities have also been demonstrated for the withania root extract (WS 100, 200 or 500 mg/kg) and potentiation of diazepam at sub-therapeutic doses (WS 50 mg/kg) have been demonstrated (Gupta and Rana 2007).

OTHER ACTIONS

Blood glucose control

Withania extract (200 and 400 mg/kg) was administered orally once daily for 5 weeks in a type 2 diabetes experimental model. The treatment reduced elevated levels of blood glucose, HbA_{1c} and insulin, and improved glucose tolerance and insulin sensitivity (Anwer et al 2008). In experimental in vitro models, withania (especially the ethanolic extract) has shown effects comparable to metformin in preventing the formation of advanced glycation end products (AGE), which are implicated in the pathogenesis of diabetes mellitus (Babu et al 2007).

Cardioprotective

Cardioprotective effects have been noted in animal studies (Dhuley 2000, Mohanty et al 2004), significantly reducing myocardial injury after ischaemia and reperfusion (Gupta et al 2004). These effects are most likely due to restoration of the myocardial oxidant–antioxidant balance and the marked anti-apoptotic properties of withania (Mohanty et al 2008). Cardioprotective effects were also observed against doxorubicin-induced cardiotoxicity in vivo when pretreatment with a standardised withania extract (300 mg/kg; 1.5% withanolides) was administered before drug exposure (doxorubicin 10 mg/kg) (Hamza et al 2008). The alkaloids are considered to be sedative and reduce blood pressure and heart rate (Chevallier 1996, Malhotra et al 1965a). The withanolides have a chemical structure similar to cardiac glycosides and have demonstrated mild ionotropic and chronotropic effects on the heart (Roja et al 1991, Tripathi et al 1996).

Antihypercholesterolaemic

High doses of withania root powder (0.75 and 1.5 g/day) produced significant decreases in total lipids (–40.54%; –50.69%), cholesterol (–41.58%; –53.01%) and triglycerides (–31.25%; –44.85%); and significant increases in HDL-cholesterol levels (+15.10%; +17.71%) in an experimental model of hypercholesterolaemia. Additionally, treatment resulted in significant decreases in HMG-CoA reductase activity and bile acid content in the liver of these animals, and there was a trend towards increased excretion of bile acid (+22.43%;+28.52%), cholesterol (+14.21%; +17.68%) and neutral sterol (+12.40%; +18.85%). Lipid-peroxidation also decreased significantly (–35.29%; –36.52%) (Visavadiya & Narasimhacharya 2007). The doses used in this study may not be feasible in humans.

Thyroid modulating

An in vivo study reported that daily administration of *W. somnifera* root extract enhanced serum T_4 concentration (Panda & Kar 1998, 1999). However, there is one case report of thyrotoxicosis in a 32-year-old woman attributed to a withania-containing herbal capsule (van der Hooft et al 2005), so caution is advised.

Sexual enhancer

Traditionally used for this purpose, one double-blind clinical trial found that a dose of 3 g taken daily for 1 year improved the sexual performance of 71.4% of healthy ageing males (Kupparajan et al 1980). Alternatively, animal studies have indicated that very high doses (3000 mg/kg) result in reduced sexual performance (Ilayperuma et al 2002).

Hepatoprotective

Animal studies have demonstrated hepatoprotective effects (Bhattacharya A et al 2000, Sudhir et al 1986) and that withania inhibits phase I, and activates phase II and antioxidant enzymes in the liver (Padmavathi et al 2005).

Anticonvulsant

Withania root extract (100 or 200 mg/kg orally) increases seizure threshold in mice. The effect is likely due to GABA-A modulation (Kulkarni et al 2008).

CLINICAL USE

Overall, *W. somnifera* has not undergone significant scientific investigation in humans, therefore much of its use is based on pharmacological effects demonstrated in experimental models or traditional usage. In practice, it is often used in herbal combination treatments.

Stress adaptation

The pharmacological effects of the herb, which have been well established in animal studies, provide a theoretical basis for its use in situations characterised by stress (Archana & Namasivayam 1999, Bhattacharya & Muruganandam 2003, Dhuley 2000, Grandhi et al 1994).

More specifically, oral administration of an aqueous, standardised extract of *W. somnifera* (in a dose extrapolated from the human dose) has been found to offer protection against experimentally induced biological, physical and chemical stressors (Rege et al 1999).

In one in-vivo study, plasma cortisol levels and adrenal weight were significantly lower, while liver weight increased (Kurandikar et al 1986).

To date, controlled studies are unavailable to determine and clarify whether these effects are also significant in humans.

(For more information see 'Clinical note — Allostasis and adaptation to stress' in the Siberian ginseng monograph.)

Anxiety

Although double-blind human studies are lacking, the herb's pharmacological effects, such as its GABA-mimetic activity (Mehta et al 1991) and ability to lower cortisol levels (Kurandikar et al 1986), provide a theoretical basis for its use in anxiety states. In vivo studies with withania root extract (WS 100, 200 or 500 mg/kg) confirm its anxiolytic effects and its ability to potentiate diazepam at subtherapeutic doses (WS 50 mg/kg) (Gupta & Rana 2007).

One study used a herbal combination treatment known as Geriforte, which contains primarily *W. somnifera*. The product was taken by 34 subjects with anxiety neurosis, and after 12 weeks significant reductions in the frequency, duration and intensity of symptoms were observed (Ghosal et al 1990).

Anabolic and weight gain promotion

Both animal and human studies have shown significant improvements in weight gain during the growth phase with the use of withania (Sharma et al 1986, Ziauddin et al 1996). It is suspected that an anabolic effect is responsible.

Withania-fortified milk (2 g/day for 60 days) has been investigated in children and found to induce weight gain, increase total plasma proteins and haemoglobin levels (Venkatraghaven et al 1980).

Anaemia

The herb is used in the treatment of iron deficiency anaemia due to its effects on haemopoeisis and natural iron content (Aphale et al 1998, Ziauddin et al 1996). This use has been supported by studies showing increased haemoglobin levels in children, induced by withania.

Cancer therapy

W. somnifera appears to reduce tumour cell proliferation while increasing overall survival time in animal trials. It enhances the effectiveness of radiation therapy while potentially attenuating the undesirable side effects of radio- and chemotherapeutic agents (including cyclophosphamide and paclitaxel) without interfering with the tumour-reducing actions of the drugs (Winters 2006).

Withania has been attributed with anti-tumour activity (Davis & Kuttan 2002, Jayaprakasam et al 2003), anti-angiogenic effects (Mathur et al 2006, Mohan et al 2004) as well as antigenotoxic effects on bone marrow (Panjamurthy et al 2008). The antioxidant effects aid in the prevention of DNA damage by mutagens (Khanam & Devi 2005) and this in combination with detoxifying properties, anti-inflammatory and immunomodulatory effects, determined in animal studies, are likely to contribute to its chemopreventive action (Prakash et al 2001, 2002).

Animal studies suggest a potential role for withania as an adjunctive treatment during chemotherapy for the prevention of drug-induced bone marrow depression (Davis & Kuttan 1999, Gupta et al 2001).

The ability to stimulate stem-cell proliferation has led to concerns that *W. somnifera* could reduce cyclophosphamide-induced toxicity and therefore reduce its usefulness in cancer therapy (Davis & Kuttan 1998). However, preliminary animal studies indicate that withania could prove to be a potent and relatively safe radiosensitiser and chemotherapeutic agent (Uma Devi 1996). In one animal experiment, pretreatment with a standardised withania extract (300 mg/kg; 1.5% withanolides) attenuated the cardiotoxic side-effects of doxorubicin (10 mg/kg) (Hamza et al 2008). In mice, the addition of *W. somnifera* (400 mg/kg orally once weekly for 4 weeks) to paclitaxel treatment (33 mg/kg intraperitoneally once weekly for 4 weeks) may extend its chemotherapeutic effect through modulating protein-bound carbohydrate levels and marker enzymes. The combination may effectively treat benzo(a)pyrene-induced lung cancer by offering protection against damage from reactive oxygen species and also by suppressing cell proliferation (Senthilnathan et al 2006a).

Drug withdrawal

In animal studies, repeated administration of withania (100 mg/kg) inhibited morphine tolerance and dependence (Kulkarni & Ninan 1997). Based on this observation, and its ability to modulate stress responses in general, withania is used in herbal combination therapy during opiate withdrawal. It may also be useful in the management of withdrawal-induced anxiety due to chronic ethanol consumption (Gupta & Rana 2008).

Arthritis

The documented anti-inflammatory, chondroprotective (Rasool & Varalakshmi 2007, Sumantran et al 2007) and antioxidant activities of withania provide some support for its traditional use in arthritis. Arthritis results from dysregulation of pro-inflammatory cytokines (e.g. TNF and IL-1 beta) and enzymes that mediate the production of prostaglandins (e.g. cyclooxygenase-2) and leukotrienes (e.g. lipooxygenase), together with the expression of adhesion molecules and matrix metalloproteinases, and hyperproliferation of synovial fibroblasts. These factors are regulated by the activation of the transcription factor nuclear factor-kappaB, which is inhibited by withanolides (Khanna et al 2007).

Withania root powder (500 and 1000 mg/kg) exerts a potent analgesic effect in rats and appears to retard amplification and propagation of the inflammatory response without causing any gastric damage (Rasool & Varalakshmi 2006).The root powder (1000 mg/kg) has also been shown to rectify biochemical changes resulting from experimentally-induced arthritis (Rasool & Varalakshmi 2007). It should be noted however that this dose is not likely to be reproducible in human trials.

Osteoporosis

An ethanolic extract of withania root markedly prevented bone loss and associated biochemical changes in ovariectomised rats indicating possible prevention of osteoporosis (Nagareddy & Lakshmana 2006). Controlled trials in humans are currently lacking.

Sleep

As its alkaloids are considered to be sedative and able to reduce blood pressure and heart rate (Chevallier 1996, Malhotra et al 1965a), withania is also used as a treatment for insomnia, although controlled trials are lacking in this area. Compared to diazepam (0.5 mg/kg) alone, the addition of withania root extract (100 mg/kg) to sleep disturbed mice significantly attenuates the negative consequences of sleep deprivation. These include; reduction in body weight,

reduced locomotor activity, anxiety and altered antioxidant status (Kumar & Kalonia 2007).

OTHER USES

Traditionally used in convalescence for people who are stressed and both physically and emotionally exhausted. It is considered a non-stimulating tonic allowing for the restoration of vitality.

In rural parts of India, withania is applied topically as an antidote to snakebite. *W. somnifera* glycoprotein inhibits the hyaluronidase activity of cobra (*Naja naja*) and viper (*Daboia russelii*) venoms providing some support for this use (Machiah et al 2006). Hyaluronidase activity is involved in rapid spreading of the toxins by destroying the integrity of the extra-cellular matrix.

DOSAGE RANGE

- Fluid extract (1:1): 20–50 mL/week (Australian manufacturer recommendations).
- Dried root: 3–6 g/day in capsule or tea form.

ADVERSE REACTIONS

Large doses can cause gastrointestinal upset, diarrhoea and vomiting (Tierra 2005).

A case report exists of thyrotoxicosis in a 32-year-old woman after taking a herbal capsule containing withania (van der Hooft et al 2005). Central nervous system and respiratory depression (Malhotra et al 1965b), decreased body temperature (Malhotra et al 1965b), gastrointestinal upset (Lindner 1996) and kidney and liver abnormalities (Arseculeratne et al 1985) have also been noted.

Acute toxicity studies in animals show a good margin of safety with a high therapeutic index (Aphale et al 1998, Rege et al 1999, Sharada et al 1993, Singh et al 2001, 2003).

SIGNIFICANT INTERACTIONS

Controlled studies are not available; therefore, interactions are based on evidence of activity and are largely theoretical and speculative.

Antipsychotic/neuroleptic agents

In animal experiments, withania has been shown to be useful in the treatment of drug-induced dyskinesia (chewing movements, tongue protrusion and buccal tremors) due to reserpine and haloperidol (Bhattacharya SK et al 2002, Naidu et al 2003, 2006). Beneficial interaction possible.

Barbiturates

Additive effects are theoretically possible leading to increased sedation (NMCD 2005, Tierra 2005). Observe patients taking withania and barbiturates concurrently — beneficial interaction possible under medical supervision.

Benzodiazepines

Based on evidence from in vivo models (Kumar & Kalonia 2007), an increased sedative effect is theoretically possible (Upton 2000). Observe patients taking withania and benzodiazepines concurrently. Beneficial interaction possible under professional supervision.

Chemotherapy

Animal studies suggest a potential role for withania as an adjunctive treatment during chemotherapy. Observe — beneficial interaction may be possible — only to be used under professional supervision.

Cyclophosphamide

While the ability to stimulate stem-cell proliferation has led to concerns that *W. somnifera* could reduce cyclophosphamide-induced toxicity and therefore reduce its usefulness in cancer therapy (Davis & Kuttan 1998), preliminary animal studies indicate that withania could prove to be a potent and relatively safe radiosensitiser and chemotherapeutic agent (Uma Devi 1996).

Doxorubicin

In rats pretreatment with a standardised withania extract (300 mg/kg; 1.5% withanolides) attenuates the cardiotoxic side-effects of doxorubicin (10 mg/kg) (Hamza et al 2008).

Paclitaxel

In mice the addition of *W. somnifera* (400 mg/kg, orally once weekly for 4 weeks) to paclitaxel (33 mg/kg, intraperitoneally once weekly for 4 weeks) may extend its chemotherapeutic effect through modulating protein-bound carbohydrate levels and marker enzymes. The combination may effectively treat the benzo(a)pyrene-induced lung cancer by offering protection from oxidative damage and also by suppressing cell proliferation (Senthilnathan et al 2006a, b).

Digoxin assays

Withania may modestly interfere with serum digoxin measurements by the fluorescent polarisation immunoassay (FPIA) and other assays (Dasgupta et al 2007, 2008).

Immunosuppressants

The ability to stimulate stem-cell proliferation has led to concerns that *W. somnifera* could reduce the effectiveness of immunosuppressant drugs (Davis & Kuttan 1998). Caution should be exercised with patients taking immunosuppressants concurrently; however, a beneficial interaction may be possible under professional supervision.

Morphine

In animal studies, repeated administration of withania (100 mg/kg) inhibited morphine tolerance and dependence (Kulkarni & Ninan 1997). For this reason it is sometimes used in opiate withdrawal. Beneficial interaction possible under professional supervision.

Thyroid medication (e.g. levothyroxine)

Additive effects are theoretically possible. An in vivo study reported that daily administration of withania enhanced serum T4 concentrations (Upton 2000) and a case report exists of withania-induced thyrotoxicosis (van der Hooft et al 2005) — observe patients taking withania and thyroid medications concurrently.

PRACTICE POINTS/PATIENT COUNSELLING

- Withania is an Ayurvedic herbal medicine also referred to as Indian ginseng or ashwaganda. Overall, it has not undergone significant scientific investigation in humans and therefore much of its use is based on pharmacological effects demonstrated in experimental models or traditional usage. It is traditionally used for improving stress adaptation responses in people who are both physically and emotionally stressed and exhausted, and during periods of convalescence.
- Preliminary evidence suggests it increases haematopoiesis, promotes weight gain, reduces anxiety symptoms, increases cognitive function and exerts a neuroprotective effect.
- It has also demonstrated antioxidant, immunomodulating, antineoplastic, antifungal and antibacterial activity in animal or test tube studies.
- The herb should not be taken in pregnancy, and used with caution in people sensitive to the Solanaceae family of plants.

CONTRAINDICATIONS AND PRECAUTIONS

Use with caution in peptic ulcer disease: withania may cause gastrointestinal irritation (Upton 2000). People who are sensitive to the Solanaceae family should use this herb with caution.

PREGNANCY USE

Contraindicated in pregnancy (Lindner 1996) due to a reputed abortifacient activity and antifertility effects noted in animal studies, despite there being no evidence of fetal damage (Mills & Bone 2005).

PATIENTS' FAQs

What will this herb do for me?

Withania has not undergone much scientific investigation in humans, so it is difficult to predict what effects will occur using this source of information. However, according to traditional usage and other studies, it may improve stress responses, reduce symptoms of anxiety, improve memory and mood, increase red blood cell production, increase immune responses and promote weight gain and is useful in convalescence.

When will it start to work?

Symptoms of anxiety and stress improve within 3 months' continual use. It is not known when other effects start to develop.

Are there any safety issues?

The herb should not be taken in pregnancy, and used with caution in people sensitive to the Solanaceae family of plants.

Zinc

BACKGROUND AND RELEVANT PHARMACOKINETICS

Zinc is an essential trace element known to play an important role in all human living cells. The human body contains approximately 2 g zinc in total, distributed across all body tissues and fluids, with 60% found in skeletal muscle and 30% in bone mass (Wahlqvist et al 2002). Its wide distribution and diverse roles have attracted the label as the 'ubiquitous nutrient' given by some authors (Hambidge 2000, King & Cousins 2006). Zinc belongs to the class of type II nutrients which are considered the cellular building blocks (Golden 1996, King & Cousins 2006) and therefore zinc, together with

the other type II nutrients (essential amino acids, magnesium, potassium, phosphorus, protein and sulfur) is required for the synthesis of any new tissue. They are not stored by the body and are under tight physiological control.

Dietary intake of zinc by healthy adults is 6–15 mg/day, however, less than half of this is absorbed (Beers & Berkow 2003). Zinc absorption is now recognised as being influenced by many factors and adequate dietary intake does not guarantee adequate zinc status. The International Zinc Nutrition Consultative Group (IZiNCG) concludes that the two key modulators of zinc bioavailability from any given diet are phytates and calcium. Foods with high phytate content significantly reduce zinc absorption due to the formation of strong and insoluble complexes (Lonnerdal 2000) and a phytate:zinc molar ratio ≥ 15, e.g. whole grains, seeds and nuts, is reported to render the zinc virtually unobtainable (IZiNCG 2004). In addition to this, calcium in large amounts constitutes the main antagonistic mineral interaction and therefore, calcium-rich diets may also precipitate zinc deficiency. Alternatively, the amount of animal protein in a meal positively correlates to zinc absorption and the amino acids histidine and methionine, and various organic acids present in foods, such as citric, malic and lactic acids, can also increase absorption. As such, zinc, similarly to iron, is best absorbed from animal food sources (King 2003).

CHEMICAL COMPONENTS

Zinc sulfate and gluconate are the most commonly used forms in supplements.

FOOD SOURCES

Meat, liver, eggs and seafood (especially oysters and shellfish) are the best sources. While zinc is also found in nuts, legumes, whole grains and seeds, the high phytate content of these foods may render them an inferior source. Phytates can be reduced through fermentation or sprouting, however, which in turn would improve zinc bioavailability in these foods. Other dietary sources include miso, tofu, brewers' yeast, mushrooms and green beans.

DEFICIENCY SIGNS AND SYMPTOMS

Severe deficiency is rarely seen in industrialised countries, but marginal deficiency and inadequate intakes are not uncommon. According to a large national survey of over 29,000 people conducted in the USA, only 55.6% had adequate zinc intakes (based on total intakes of >77% of the 1989 US recommended daily intake (RDI) levels). Young children aged 1–3 years, female adolescents and older people aged ≥71 years had the lowest percentage of 'adequate' zinc intake, and were identified at greatest risk of deficiency (Briefel et al 2000). Others at risk are alcoholics (especially those with liver disease), pregnant and lactating women, teenagers experiencing rapid growth, malnourished individuals including those with anorexia nervosa, people with severe or chronic diarrhoea, malabsorption syndromes or inflammatory bowel diseases, and strict vegetarians.

Zinc repletion facilitates growth and replication of individual cells and the organism at large. Consequently, the frank deficiency picture is characterised by impaired growth (linear growth velocity, weight or body composition) (Hambidge 2000). This will produce overt presentations in those life stages and tissues necessitating rapid replication and turnover for health (Hambidge 2000), e.g. embryos, early childhood, adolescence, immune cells, epidermal and gastrointestinal tissue (Hambidge 2000, IZiNCG 2004, King 2000, King & Cousins 2006, Mahomed et al 1993), but often indiscernible pictures outside of these. The clinical picture of mild zinc deficiency is subtle, ambiguous, idiosyncratic (Golden 1996, Hambidge 2000) and notoriously difficult to diagnose (Golden 1996, Wood 2000). A prominent zinc researcher says, 'the ubiquity and versatility of zinc in subcellular metabolism suggest that zinc deficiency may well result in a generalised impairment of many metabolic functions' (p. 1345S) (Hambidge 2000).

Signs and symptoms of deficiency

Most consistently reported:

- Anorexia, impaired sense of taste and smell.
- Slowed growth and development.
- Delayed sexual maturation, hypogonadism, hypospermia and menstrual problems.
- Dermatitis, particularly around the body's orifices as seen in acrodermatitis enteropathica.
- Alopecia.
- Chronic and severe diarrhoea.
- Immune system deficiencies and increased susceptibility to infection, including bacterial, viral and fungal.
- Impaired wound healing due to decreased collagen synthesis.
- Night blindness; swelling and clouding of the corneas.
- Behavioural disturbances such as mental fatigue and depression (King 2003).

Less consistently reported:

- Erectile dysfunction.
- Anergy.
- Glossitis.
- Nail dystrophy.
- Hypopigmented hair.
- Photophobia.
- Photic injury.
- Swelling and clouding of the corneas.
- Reduced serum testosterone in males.
- Reduced alcohol clearance.
- Hyperammonaemia.
- Impaired protein synthesis.

Zinc deficiency in pregnancy is associated with the following (Bedwal & Bahuguna 1994, Prasad 1996):

- Increased maternal morbidity, pre-eclampsia and toxaemia.
- Prolonged gestation.
- Inefficient labour.
- Atonic bleeding.
- Increased risk of abortion and stillbirths.
- Teratogenicity.

- Low birth weight infants.
- Diminished attention in the newborn and poorer motor function at 6 months (Higdon 2003).

Primary deficiency

This can result from inadequate dietary intake of zinc, for example, strict vegetarians and vegans are at risk of deficiency if their major food staples are grains and legumes, due to their phytate content. Premature and low birth weight infants, pregnant women, adolescents and the elderly are also at risk of inadequate intake, often in the face of increased demands (Briefel et al 2000).

Secondary deficiency

Impaired zinc absorption is also a common cause of zinc deficiency (Lonnerdal 2000), for example in some people with cirrhosis and malabsorption syndromes. Other conditions produce increased losses of zinc, e.g. severe burns, major surgery, chronic diarrhoea, diabetes, HIV and AIDS, and during prolonged parenteral nutrition (Prasad et al 1999). Additionally, strenuous exercise and elevated ambient temperatures increase zinc losses through perspiration. A rare congenital disorder known as acrodermatitis enteropathica, which typically manifests 4–6 weeks after weaning, indicates a significantly compromised ability to absorb zinc forms other than that which is present in breast milk. Consequently, prior to diagnosis and life-long supplementation, infants or children suffering this condition rapidly develop signs of severe zinc deficiency which include the key features listed above, e.g. dermatitis, growth retardation, diarrhoea and alopecia.

MAIN ACTIONS

Important co-factor in many biochemical reactions

In humans, zinc metalloenzymes outnumber all the other trace mineral-dependent enzymes combined, with between 70 and 200 present in humans (Gropper et al 2009), found across all six different enzyme classes (Hambidge 2000). Consequently,

Clinical note — Measuring zinc status is difficult

According to the scientific evidence, there is currently no means of assessing zinc status in humans (particularly with respect to the detection of marginal deficiency states) that has demonstrated absolute accuracy, and the identification of such a test has been flagged as an area requiring urgent research (Bales et al 1990, Hambidge 2000, IZiNCG 2004, Wood 2000). The assessment of zinc in orthodox medicine currently utilises serum or plasma assays (Gropper et al 2009, IZiNCG 2004, Wood 2000). Principally validated as a tool to assess zinc adequacy of populations (IZiNCG 2004, Wood 2000), serum/plasma zinc lacks the sensitivity to accurately ascertain the zinc status of the individual, with decreased values reflective of end-stage depletion only (Gordon et al 1982, Gropper et al 2009, Hambidge 2000, 2003, IZiNCG 2004, Wood 2000). Multiple established confounding variables include diurnal variation, concomitant infections and inflammation, acute stress and trauma, haemodilution of pregnancy, low-serum albumin, high white blood cell counts and the concomitant use of hormones and steroids (King & Cousins 2006, Wood 2000). Each of these scenarios is susceptible to producing false negatives, underpinning concerns regarding the specificity of serum/plasma zinc assessment (Hambidge 2003, Hotz et al 2003). In addition to this, data from the National Health and Nutrition Examination Survey (NHANES II) revealed significant differences in the mean values of 'healthy individuals' dependent on age and sex alone (IZiNCG 2004). In spite of these documented limitations, this test remains the first line assay in orthodox medicine.

A range of other biochemical indices have been used to assess zinc, including red (Kenney et al 1984, Prasad 1985) and white blood cells (Bunker et al 1987, Prasad 1985), platelets (Baer & King 1984), hair (Bunker et al 1987, Erten et al 1978, Hambidge 2003, McBean et al 1971, McKenzie 1979), nails (McKenzie 1979), saliva (Bales et al 1990, Freeland-Graves et al 1981, Greger & Sickles 1979), sweat (Baer & King 1984, Eaton et al 2004) and urinary concentrations (Hambidge 2003, McKenzie 1979, Prasad 1985). All represent static measures and, as such, lack the sensitivity required to account for zinc's dynamic and complex homeostasis (Gropper et al 2009). Many researchers believe that an accurate indicator of zinc nutriture will therefore also need to be dynamic, similar to using ferritin as a marker for iron status (Hambidge 2000, Hambidge 2003, Wood 2000).

One area of functional zinc assessment extensively researched since the 1970s is taste acuity testing (Gibson 1990, Gibson et al 1989, Henkin et al 1975b,). Hypogeusia is recognised as an early indicator of zinc deficiency (Buzina et al 1980, Gibson 1990, Henkin et al 1975a, Kosman & Henkin 1981, Tanaka 2002, Wright et al 1981) and is believed to be the result of compromised gustin activity, a carbonic anhydrase zinc metalloenzyme, which facilitates differentiation, growth and turnover of taste buds (Gibson et al 1989, Henkin et al 1975b, 1977, Law et al 1987, Thatcher et al 1998). The zinc taste response test (also known as the Bryce-Smith taste test) is a popular measure among naturopathic practitioners. It relies on patients detecting a taste after oral administration of 5–10 mL of a zinc sulfate heptahydrate solution. Delayed taste perception or lack of taste recognition is interpreted as a zinc deficiency state. This method is not particularly accurate and is hampered by variations in patients' subjective sense of taste and the fact that agents other than zinc influence taste perception. Clinical studies with zinc taste tests have confirmed the inconsistency of the results (Birmingham et al 2005, Eaton et al 2004, Garg et al 1993, Mahomed et al 1993).

zinc is involved in myriad chemical reactions that are important for normal body functioning, such as carbohydrate metabolism, protein and DNA synthesis, protein digestion, bone metabolism and endogenous antioxidant systems (Merck 2009, Wahlqvist et al 2002, Wardlaw et al 1997). At the cellular level, zinc's functions can be divided into three categories: catalytic, structural and regulatory (King 2003). Zinc ions perform structural roles in a range of proteins and biomembranes. Of particular note is the zinc finger motif which occurs in transcriptional proteins, directing their binding to DNA and subsequent gene expression. The zinc ion is considered to play the key role in this interaction (Hambidge 2000). Zinc's contribution as an intra- and intercellular regulatory ion continues to emerge and currently includes its influence upon gene expression, receptor-mediated signal transduction, antigen-dependent T-cell activation, insulin-like growth factor receptor binding and glutamatergic activity in the central nervous system (Hambidge 2000, King & Cousins 2006). In its catalytic capacity, zinc metalloenzymes are defined as those apometalloenzymes which are dependent upon the binding of zinc for their activity.

Growth and development

Zinc is important for the formation of biomembranes and zinc finger motifs found in DNA transcription factors (Semrad 1999) and, belonging to the type II nutrient class, is required for the building of all new tissues.

Normal immune responses

Zinc is involved in many aspects of immunological function. It is essential for the normal development and function of cells, for mediating non-specific immunity such as neutrophils and natural killer cells and for affecting development of acquired immunity and T-lymphocyte function. Deficiency primarily impacts on T-lymphocyte function, reducing both peripheral numbers and thymic cells, compromising function of the T helper and cytotoxic cells and reducing serum levels of thymulin. In addition to this, zinc depletion rapidly diminishes antibody and cell-mediated responses in both humans and animals, all together leading to increases in opportunistic infections and mortality rates (Fraker et al 2000). Animal models have shown that suboptimal intake of zinc over 30 days can lead to 30–80% loss in defence capacity. Investigation using a human model has demonstrated that even mild deficiency in humans adversely affects T-cell functions (Prasad 1998). Conversely, high-dose zinc supplementation (20-fold RDI) can also produce immune dysfunction due to an induced copper deficiency. Zinc supplementation also influences cytokine production with reduced tumour necrosis factor (TNF)-alpha and interleukin (IL)-beta in healthy adults (Overbeck et al 2008).

Neurological function

Zinc ions are unevenly distributed in the central nervous system (CNS), acting as neurosecretory products or co-factors. Zinc is highly concentrated in the synaptic vesicles of specific neurons, known as 'zinc-containing' neurons (Frederickson & Danscher 1990, Frederickson & Moncrieff 1994, Frederickson et al 2000). Zinc-containing neurons are a subset of glutamatergic neurons and are mostly located in the telencephalon. Zinc is released from zinc-containing neurons in a calcium- and impulse-dependent manner, producing a broad spectrum of neuromodulatory effects. Additionally, zinc appears to stabilise the storage of certain macromolecules in presynaptic vesicles.

Reproduction

In humans, zinc is necessary for the formation and maturation of spermatozoa, for ovulation and for fertilisation (Favier 1992). Zinc has multiple actions on the metabolism of androgen hormones, oestrogen and progesterone, and these, together with the prostaglandins and nuclear receptors for steroids, are all zinc finger proteins.

In adult males, zinc content is high in the testis and prostate, which have the highest concentration of zinc of any organ in the body (Bedwal & Bahuguna 1994).

In women, zinc deficiency in pregnancy has been associated with increased maternal morbidity, increased risk of abortion, stillbirth, teratogenicity and other unwanted outcomes (Bedwal & Bahuguna 1994).

Antioxidant

Zinc limits oxidant-induced damage in a number of indirect ways, such as by protecting against vitamin E depletion, controlling vitamin A release, contributing to the structure of the antioxidant enzyme extracellular superoxide dismutase, restricting endogenous free radical production, maintaining tissue concentrations of metallothionein, a possible scavenger of free radicals, and stabilising membrane structure (DiSilvestro 2000). It was observed to decrease lipid peroxidation and protect mononuclear cells from TNF-alpha-induced NF-kappa-B activation associated with oxidative stress (Prasad et al 2004).

Insulin-like activity

One of the in vivo features of zinc is its insulin-like function, which is mediated via inhibition of endogenous GSK-3 (Ilouz et al 2002). This is important because GSK-3 inhibition appears essential for normal function of the insulin-activated signalling pathway.

CLINICAL USE

Many of the clinical uses of zinc supplements are for conditions thought to arise from a marginal zinc deficiency, but some indications are based on the concept that high-dose zinc supplements act as a therapeutic agent above and beyond the point of repletion.

Deficiency

Traditionally, zinc supplementation has been used to treat deficiency or prevent deficiency in conditions such as acrodermatitis enteropathica, anorexia

nervosa, malabsorption syndromes, conditions associated with chronic diarrhoea, alcoholism, diabetes, HIV and AIDS, recurrent infections, severe burns, Wilson's disease and sickle cell anaemia. Zinc supplements are also popular among athletes in order to counteract zinc losses that occur through perspiration.

Common cold

Oral zinc supplements, lozenges, nasal sprays and gels have been investigated in the treatment of the common cold. It has been demonstrated that a transient increase in zinc concentrations in and around the nasal cavity prevents rhinovirus binding to cells and disrupts infection (Novick et al 1996) and/or modulates inflammatory cytokines and histamine release that may exacerbate cold symptoms (Kurugöl et al 2007). Additionally, there is evidence to suggest that zinc inhibits viral replication.

Nasal preparations

A randomised, double-blind, placebo-controlled trial with 160 people tested the effects of a nasal spray of 0.12% zinc sulfate and found that it reduced the total symptom score, but had no effect on the duration of cold symptoms or the mean time to resolution (Belongia et al 2001). The effectiveness of intranasal zinc gluconate as a preventative agent against experimentally induced rhinovirus infection was tested in a study of 91 subjects (Turner 2001). It was administered for 3 days prior to rhinovirus inoculation followed by 6 days of treatment. This regimen had no effect on total symptom score, rhinorrhoea, nasal obstruction or the proportion of infected volunteers who developed clinical colds.

Two other trials using a dose of zinc in a nasal gel formulation showed that zinc treatment significantly reduced cold duration compared with placebo when used within 24–48 h of symptom onset (Hirt et al 2000, Mossad 2003). The nasal gel spray contained either 33 mmol/L zinc gluconate or placebo and was administered as one dose per nostril four times daily until symptoms resolved or for a maximum of 10 days. Symptoms that responded included nasal drainage, hoarseness and sore throat (Mossad 2003).

Oral supplements

Both positive and negative results have been obtained for different forms of oral zinc supplements and lozenge preparations. A 2000 Cochrane review analysed the results from seven trials involving 754 cases and concluded that current evidence is inconclusive as to whether zinc lozenges are an effective treatment for symptoms of the common cold (Marshall 2000). This conclusion is considered conservative, as an intention-to-treat analysis at 7 days found a statistically significant relative risk (RR) of 0.69, and the numbers needed to treat for one person to benefit ranged from 4 to 8 (Arroll 2005). The authors of the review were concerned about blinding of the studies and variation in doses used, making a conclusive recommendation difficult.

Since then, several new studies have been published (Eby & Halcomb 2006, McElroy & Miller 2002, 2003, Turner & Cetnarowski 2000). McElroy and Miller (2002) showed that treatment with zinc gluconate glycine lozenges (Cold-Eeze) significantly decreased cold duration (7.5 vs 9.0 days for non-use) and significantly reduced cold frequency and concomitant antibiotic use in school-aged subjects. A subsequent phase IV study by the same pair of researchers (2003) investigated the therapeutic and prophylactic effectiveness of Cold-Eeze for the common cold in a cohort of 134 subjects drawn from the previous study. Once again, zinc gluconate glycine lozenges shortened cold duration (6.9 vs 9.0 days) and the mean number of colds (1.7 vs 1.28), achieving a 25% reduction in cold incidence. Zinc lozenges were administered once daily during the cold season and four times daily as acute treatment. An adult study demonstrated that zinc gluconate (13.3 mg) or zinc acetate (5 or 11.5 mg) lozenges had no effect on duration or severity of cold symptoms (Turner & Cetnarowski 2000). A double-blind, placebo-controlled study found that frequent administration of zinc orotate lozenges (37 mg zinc each) and intranasal zinc gluconate spray had no effects on severity of cold symptoms or their duration (Eby & Halcomb 2006). Another positive finding resulted from a study of oral zinc sulfate syrup administration to 120 otherwise healthy and zinc-replete children aged 1–10 years (median age 5) (Kurugöl et al 2007). A daily dose of 30 mg of elemental zinc was given within 24–48 h after the onset of cold symptoms to those children randomly selected for the treatment group, producing a reduction in symptom severity from day 2. Nasal symptoms were the most significantly improved in those taking zinc; however, the duration of these or other symptoms was not different between the two groups. The study authors note that, in light of the normal serum zinc results at baseline, the actions of zinc are not associated with deficiency correction.

It is not clear why some trials have produced positive results whereas others have not; however, it is suspected that the type of zinc and administration regimen has an influence over effectiveness. A closer look at the evidence shows that zinc gluconate and zinc acetate are the forms generally associated with positive results, whereas other forms are less effective. Additionally, lozenge additives such as sorbitol and citric acid are thought to decrease zinc ion release, which is necessary for zinc's virucidal activity. It has been suggested that zinc lozenges be allowed to completely dissolve in the mouth without chewing and that citrus fruits or juices be avoided 30 min before or after dissolving each lozenge to avoid negating the therapeutic effects of zinc (Silk & LeFante 2005).

Reduced frequency of infections in elderly

Both zinc deficiency, due to poor dietary intake, and impaired cell-mediated immunity are commonly reported in the elderly (>55 years) and have been used to explain the increased infection rates observed in this population. A small randomised double-blind study of zinc supplementation was

undertaken in 50 healthy elderly subjects (Prasad et al 2007). At baseline, plasma zinc values indicated that the majority had a marginal zinc deficiency, while 35% were below the cut-off for frank deficiency. Zinc gluconate supplementation, providing a total daily elemental amount of 45 mg via two divided doses, or placebo was undertaken for 12 months. Those individuals in the treatment group demonstrated a significant reduction in infection incidence (29% vs 88%), with protective effects evident, for example, against upper respiratory tract infections (12% vs 24%), the common cold (10% vs 40%) and influenza (0% vs 12%). Also of note, while no individual in the treatment group experienced more than one infection in the 12-month period, six individuals taking placebo had two infections, and three subjects had three or more infections during the same period. Inflammatory cytokines and markers of oxidative stress were also investigated in this study, confirming zinc's role as both an anti-inflammatory and an antioxidant in the elderly.

Age-related macular degeneration (ARMD)

Both dietary and supplemental zinc have been investigated in the prevention and/or delayed progression of ARMD. A 2005 study found that high dietary intake of zinc, beta-carotene and vitamins C and E was associated with a 35% reduced risk in elderly persons (van Leeuwen et al 2005). Similarly, the Blue Mountains Eye Study, an Australian prospective population-based cohort study conducted over 10 years, demonstrated protective effects of lutein and zeaxanthin but also found that those individuals consuming the highest zinc had an RR of 0.56 for any ARMD and 0.54 for early ARMD compared with all other participants (Tan et al 2008). An interesting study has revealed that increased lifetime exposure to blue light appears to amplify the risk of low dietary antioxidants and zinc (Fletcher et al 2008). Originally believed to simply act as an antioxidant in this condition, ongoing discussions of zinc's possible actions in the prevention of this aetiology have produced new hypotheses.

Smoking has long been established as one of the few independent risk factors for ARMD and a direct association between risk and the number of cigarettes smoked has been elucidated (Coleman et al 2008, Wills et al 2008a). It was revealed that smokers have a four times greater retinal concentration of cadmium than non-smokers and that the associated morphological changes are reasonably consistent with ARMD pathology (Wills et al 2008a). A comparison of zinc and copper concentrations within the retinal pigment epithelium (RPE) and choroid complex of eye donor subjects previously suffering from ARMD and those without the condition has revealed a 23–24% reduction in these metals in afflicted subjects (Erie et al 2009). Furthermore, in vitro studies confirm that zinc and copper, as well as manganese (the latter being most potent), effectively prevent the intracellular concentration of cadmium in retinal tissues and hence modulate its toxicity (Satarug et al 2008, Wills et al 2008b). Taken together with the knowledge that zinc and copper supplementation, in combination with antioxidants, has delayed progression of ARMD, points towards a critical role for metal homeostasis in retinal health.

A 2006 Cochrane review assessed the effects of antioxidant vitamin and/or mineral supplementation on the progression of ARMD and found that evidence of effectiveness is currently dominated by one large trial that showed modest benefit in people with moderate to severe signs of the disease who were administered antioxidant vitamins and zinc together (Evans 2002). The study the authors refer to is the Age-Related Eye Disease Study (AREDS 2001), which showed that high-dose vitamins C and E, beta-carotene, and zinc supplementation delayed the progression from intermediate to advanced disease by 25% over 5 years. The 11 centre, double-blind, prospective study involved 3640 volunteers aged between 55 and 80 years who were randomly divided into four treatment groups, receiving either antioxidant supplements (500 mg vitamin C, 400 international units (IU) vitamin E, and 15 mg beta-carotene daily), zinc oxide and cupric oxide (80 mg elemental zinc, 2 mg elemental copper daily), antioxidants plus zinc, or placebo. The contribution of zinc to this result is unknown (see Lutein monograph for more information about ARMD); however, AREDS2 is currently underway, employing a reduced dose of zinc, in light of interim evidence that a smaller dose may be efficacious and is less likely to produce adverse effects (Coleman et al 2008).

An RCT administered zinc monocysteine (25 mg elemental zinc twice daily) as a stand-alone treatment to 80 ARMD patients over 6 months (Newsome 2008). Those in the treatment group experienced improved visual acuity, contrast sensitivity and reduced macular light flash recovery time when compared with the placebo group, with some benefits evident 3 months into the treatment.

Overall, current evidence suggests that zinc supplementation, either alone or in combination with other antioxidants, may help to prevent ARMD in those at least at moderate risk and delay progression of this condition in those suffering the early stages. Additional emerging evidence suggests an interaction between genetics and responsiveness to zinc as a treatment in ARMD sufferers, with retrospective analyses of the AREDS study demonstrating a strong interaction between those individuals whose progression of the condition was delayed by zinc supplementation and the presence of the complement factor H (CFH) genotype (Klein et al 2008, Lee & Brantley 2008). Substantiation of these findings could assist in the improved targeting of ARMD nutritional therapies.

Diabetes mellitus (T1DM and T2DM)

Zinc is abundant in the pancreas due to extensive roles in both its endocrine and its exocrine functions. During deficiency, this is one of the few tissues that demonstrates reduced concentrations of this mineral (Islam & Loots 2007). Limited data derived from both epidemiological studies and animal models suggest that increased dietary zinc intake may be protective against the development

of both types of diabetes (Bolkent et al 2009, Islam & Loots 2007, Sun et al 2009). Current thoughts regarding zinc's actions in this condition are that attributed to an antioxidant role, conveyed both directly and indirectly, via metallothionein induction (Islam & Loots 2007). Decreasing oxidative stress, zinc would thereby protect beta cells from damage and also assist in maintaining normal insulin secretion.

Zinc supplementation is sometimes used in order to avoid deficiency, a state associated with both T1DM and T2DM (Cunningham et al 1994). It remains unclear, however, whether zinc repletion or using high-dose zinc to induce other effects will be beneficial in the clinical management of diabetes, its complications or its prevention, as current data from both animal and human studies have produced varied results (Baydas et al 2002, Cunningham et al 1994, Farvid et al 2004, Gupta et al 1998, Niewoehner et al 1986, Roussel et al 2003, Tobia et al 1998).

Several intervention studies of oral zinc have produced positive results in T1DM populations, with evidence of reduced glycated haemoglobin amongst individuals in one treatment group (30 mg/day elemental zinc for 3 months) vs the control group (Al-Maroof & Al-Sharbatti 2006), improved blood lipid profiles following 12 weeks of zinc treatment (100 mg/day zinc sulfate) in another study (Partida-Hernández et al 2006) and improved glycaemic control and diabetic neuropathy in 20 patients administered 660 mg/day zinc sulfate over 6 weeks (Hayee et al 2005).

With respect to T2DM, a prospective, double-blind, clinical interventional study of 56 obese women with normal glucose tolerance randomised subjects to treatment with zinc, 30 mg/day, or placebo for 4 weeks (Marreiro et al 2002). Zinc treatment decreased insulin resistance from 5.8 to 4.3 and insulin decreased from 28.8 to 21.2 mU/mL, but was unchanged in the placebo group. These results are particularly noteworthy because the women were not zinc deficient, suggesting a therapeutic role for zinc. Another small study of metformin-resistant T2DM patients administered zinc (zinc acetate 50 mg/day) in combination with melatonin (10 mg/day) ± metformin to two treatment groups and placebo to a third (Hussain et al 2006). This combined treatment proved effective in improving fasting and postprandial glucose levels and augmented the action of the hypoglycaemic drug. Further studies with larger sample sizes are required to validate zinc as an effective treatment in T1DM and T2DM and elucidate the optimal dosing and administration regimen.

Clinical note — Zinc deficiency and diabetes

Diabetes affects zinc homeostasis in many ways and is associated with increased urinary loss, decreased absorption and decreased total body zinc (Chausmer 1998, Cunningham et al 1994). The role of zinc and zinc deficiency in diabetes and its complications or prevention is currently unclear. It has been suggested that deficiency may exacerbate destruction of islet cells in T1DM and may adversely affect synthesis, storage and secretion of insulin, a process that requires zinc. Furthermore, evidence indicates that T1DM patients have a higher concentration of free radicals than healthy controls, which is due to increased oxidant production and/or decreased efficiency of endogenous antioxidant systems (Davison et al 2002). It is suspected that deficiency of key micronutrients (i.e. zinc, copper, manganese and selenium), which are integral components of important antioxidant systems, may be partly responsible.

Improves wound healing

Zinc is an essential co-factor in both wound healing and immune function. Therefore, zinc deficiency retards both fibroplasia and epithelialisation, and results in delayed wound healing in spite of maintained skin stores of zinc, except in instances of severe concomitant protein restriction (Lansdown et al 2007). Zinc supplements are used to restore zinc status in cases of wound healing associated with malnutrition and deficiency. Additionally, zinc administered orally or topically to wounds can promote healing and reduce infection, according to one major review (Lansdown 1996).

Oral application

In 2001, a randomised study demonstrated that oral zinc sulfate significantly improved healing of cutaneous leishmaniasis (Sharquie et al 2001). Results showed that the cure rate for a dose of 2.5 mg/kg was 83.9%, for 5 mg/kg it was 93.1% and for 10 mg/kg it was 96.9%, whereas no lesions showed any sign of healing in the control group. The results of several studies suggest a specific role for oral zinc in surgical wound repair (Lansdown et al 2007). Zinc redistribution and sequestration in the liver occur following both surgical trauma and infection. The corresponding reduction in serum zinc may then impair the individual's healing capacity, as demonstrated in a study of 80 total hip replacement patients (mean age 66 years), in whom serum zinc levels were significantly related to rates of infection and dehiscence (Lansdown et al 2007). Similarly, an interventional study of pre- and postoperative zinc infusion (30 mg/day) in patients undergoing major vascular reconstructive surgery attenuated the anticipated decline in serum zinc and produced significantly fewer wound-healing complications than placebo.

Topical application

Theoretically, topical zinc treatment is most suited to human wound healing that necessitates epithelialisation, e.g. suction blister wound, superficial small incision and split thickness skin graft donor sites. While clinical trials have demonstrated its efficacy in relation to treatment of leg ulcers, pressure ulcers, diabetic foot ulcers and burn wounds (Lansdown et al 2007), one study also demonstrated that *Staphylococcus aureus* was cultured significantly less frequently in zinc oxide treated wounds, which points to the additional antiseptic action. Topical

zinc oxide promotes cleansing and re-epithelialisation of ulcers and reduces the risk of infection and deterioration of ulcers compared with placebo, according to one double-blind trial of leg ulcer patients with low-serum zinc levels (Agren 1990). Evidence from animal and in vitro research suggests that topically applied zinc solution is more effective when combined with iron than when used alone, and can effectively enhance healing in acute partial-thickness and second-degree burn wounds (Feiner et al 2003). The form of zinc used topically may be of marked importance, with some studies investigating high concentrations of zinc sulfate delaying healing and increasing dermal inflammatory cell infiltration (Lansdown et al 2007). Preparations such as zinc oxide may be more suitable than readily water-soluble forms, providing a sustained release of bioavailable zinc at non-cytotoxic levels. Interestingly, pharmacopoeias attribute various zinc forms with different qualities/actions, e.g. zinc sulfate is regarded as a local astringent and antiseptic, insoluble zinc oxide as a mild antiseptic, astringent and protective agent, particularly indicated in inflamed skin and wounds.

Arterial and venous leg ulcers

Chronic leg ulcer patients often exhibit abnormal zinc metabolism and depressed serum concentrations (Lansdown et al 2007). A 2000 Cochrane review assessed six placebo-controlled trials of zinc sulfate supplementation (≥220 mg administered three times daily) in arterial and venous leg ulcers and concluded that, overall, there is no evidence of a beneficial effect on the number of ulcers healed. However, there is some evidence that oral zinc might improve healing of venous ulcers in people with low-serum zinc levels (Wilkinson & Hawke 2000).

Double-blind studies producing encouraging results have used oral zinc (600 mg/day) combined with topical treatment and compression bandages (Haeger & Lanner 1974, Hallbook & Lanner 1972).

Acne and other skin conditions

Over the past 2–3 decades, tetracyclines and macrolide antibiotics have been widely prescribed for the treatment of acne; however, resistance has been reported, especially to erythromycin and clindamycin with cross-resistance being widespread among strains of *Propionibacterium acnes*. As a result, non-antibiotic treatments such as topical and oral zinc preparations have been investigated as both alternatives and adjuncts to these treatments.

Overall, studies have yielded conflicting results, possibly due to considerable placebo effects, with better effects generally seen on inflammatory lesions than other lesion types. This is most likely due to the fact that zinc has a marked anti-inflammatory effect, which was first observed with zinc sulfate and later with zinc gluconate, which is a better tolerated form.

Oral supplementation

Numerous studies have been conducted investigating the effects of zinc supplementation in acne vulgaris (Dreno et al 1989, 1992, 2001, Goransson et al 1978, Hillstrom et al 1977, Orris et al 1978, Weimar et al 1978, Weismann et al 1977, Verma et al 1980). Doses between 90 mg and 200 mg (30 mg elemental zinc) daily taken over 6–12 weeks have been associated with generally positive results, whereas larger doses tend to be poorly tolerated. An open study involving 30 subjects with inflammatory acne found that a lower dose of oral zinc gluconate (30 mg) taken daily reduced the number of inflammatory lesions after 2 months, regardless of whether *P. acnes* was present (Dreno et al 2005).

Two double-blind studies have compared the effects of oral zinc supplementation with two antibiotic medicines, minocycline or oxytetracycline, over 3 months (Cunliffe et al 1979, Dreno et al 1989). Zinc sulfate (135 mg) was as effective as oxytetracycline after 12 weeks' use, decreasing acne scores by 65% in one study, whereas the same dose was not as effective as minocycline (500 mg) in the second study.

Zinc has also been investigated as an adjunct to antibiotic therapy under laboratory conditions. When administered in combination with erythromycin, it inhibits erythromycin-resistant propionibacteria according to two in vitro studies (Dreno et al 2005, Oprica et al 2002).

Topical application

A number of studies have investigated the effects of a topical erythromycin–zinc acetate formulation (Bojar et al 1994, Feucht et al 1980, Habbema et al 1989, Morgan et al 1993, Pierard & Pierard-Franchimont 1993, Pierard-Franchimont et al 1995, Schachner et al 1990)

Statistically significant effects have been observed within the first 12 weeks of treatment for acne severity grades, and for papule, pustule and comedo counts, with the effect of the combination superior to preparations containing erythromycin alone (Habbema et al 1989, Schachner et al 1990). Human studies have identified antibacterial activity against *Propionibacterium* spp. in short-term treatment, which is mostly attributed to zinc (Fluhr et al 1999) and sebosuppressive effects (Pierard & Pierard-Franchimont 1993).

Reduced male fertility

Zinc deficiency leads to several clinical signs, such as decreased spermatogenesis and impaired male fertility and, given zinc's pivotal role in DNA transcription, this is not surprising. Furthermore, zinc finger proteins are critical to the genetic expression of steroid hormone receptors. Together with zinc's additional anti-apoptotic and antioxidant actions, these effects make zinc a promising contributor to healthy sperm (Ebisch et al 2007). The relationship between zinc concentrations in seminal fluid and semen fertility, however, remains somewhat unclear.

When zinc deficiency is not present, a 2002 survey found no statistically significant relationship between zinc in seminal plasma or serum and semen quality or local antisperm antibody of the IgG or IgA class (Eggert-Kruse et al 2002). Furthermore, zinc levels did not influence sperm capacity to penetrate cervical mucus in vitro or in vivo, nor affect

subsequent fertility. However, a study of Chinese men (aged 20–59 years) revealed that when serum zinc concentration was low, the risk of asthenozoospermia increased and the Cu/Zn ratio was higher in those with progressive motility abnormalities (Yuyan et al 2008).

In addition to this, a small number of both animal (Kumar et al 2006) and human supplementation studies (Ebisch et al 2006) have produced contrastingly positive results. The latter study involved 40 sub-fertile and 47 fertile men treated for 26 weeks with 66 mg/day zinc sulfate and 5 mg/day folic acid or placebo, producing a 74% increase in normal sperm count in the sub-fertile subjects; however, more studies with larger sample sizes are required to substantiate these preliminary findings.

Impotence

In men, zinc deficiency may lead to impaired testosterone synthesis, resulting in hypogonadism and impotency. One placebo-controlled study has investigated whether oral zinc supplementation improves erectile dysfunction. The study involved 20 uraemic haemodialysis patients and showed that 6 months treatment with oral zinc acetate (25 mg elemental zinc) taken twice daily 1–2 h before meals resulted in greater libido, improved potency and more frequent intercourse compared to placebo (Mahajan et al 1982). Active treatment also resulted in significant increases in plasma zinc, serum testosterone and sperm count and decreases in serum levels of luteinising hormone (LH) and follicle stimulating hormone (FSH).

Attention-deficit hyperactivity disorder

Zinc deficiency has been implicated in the pathogenesis of attention deficit hyperactive disorder (ADHD) from numerous perspectives. With a critical role in neurological development and evidence of impaired learning and depressed psychomotor retardation in deficiency states, zinc may constitute a direct aetiological cause (Black 2003, Fanjiang & Kleinman 2007). An interesting longitudinal paediatric study found that children with malnutrition (protein, zinc and iron deficiencies) at 3 years of age demonstrated higher externalisation behaviour problems at 8, 11 and 17 years, when compared to replete children (Liu & Raine 2006), with this trifecta of deficiencies, a particularly common combination in young children.

Hypotheses of indirect actions of zinc deficiency include negative behavioural effects mediated via impaired fatty acid metabolism and through the exacerbation of heavy metal effects.

In 1990, Arnold et al observed that boys aged 6–12 years with ADHD and a higher baseline hair zinc level had better responses to amphetamine therapy than children with hair concentrations indicative of mild zinc deficiency. At the time, it was suggested that poor/non-responders to drug therapy and those presenting with suboptimal zinc status would require zinc supplementation instead of amphetamine treatment to address the condition. Since then, numerous controlled studies have identified that children with ADHD have lower zinc tissue levels (serum, red cells, hair, urine, nails) than normal children (Arnold & DiSilvestro 2005). It is not certain why this occurs, but may result from not sitting at the kitchen table long enough to consume a balanced diet, picky eating, stimulant-related appetite suppression, malabsorption or biochemical changes. Since then, zinc status has been also shown to correlate with the amplitude and latency of select brain waves, suggesting that zinc may particularly influence information processing in ADHD children (Yorbik et al 2008).

Three double-blind studies, all conducted in middle-eastern populations, have investigated whether oral zinc supplementation has a beneficial effect in ADHD, producing promising results. One randomised study involving 400 Turkish children with a mean age of 9.6 years found that treatment with 150 mg zinc sulfate (equivalent to 40 mg of elemental zinc) daily for 12 weeks resulted in significant reductions in hyperactive, impulsive and impaired socialisation features, but not in reducing attention deficiency symptoms, as assessed by the ADHD Scale (Bilici et al 2004). A significant difference between zinc and placebo was already evident by week 4 ($P = 0.01$). Older children with low zinc and free fatty acid levels and high body mass index (BMI) responded best to treatment. A second placebo-controlled trial used a combination of 55 mg zinc sulfate (equivalent to 15 mg elemental zinc) and methylphenidate (1 mg/kg) daily for 6 weeks in Iranian children aged 5–11 years and reported significant benefits with the combination (Akhondzadeh et al 2004). Zinc (15 mg/day elemental) or placebo was administered to 218 grade three students in a low-income district of Turkey over 10 weeks, resulting in a reduced prevalence of clinically significant ratings of attention deficit and hyperactivity in the treatment group (Uçkardeş et al 2009).

It is important to note that these studies were conducted with children from countries with suspected widespread zinc deficiency and further investigation is required to determine whether the same beneficial results will occur in children living in Western countries.

Depression

Epidemiological evidence has revealed an inverse relationship between serum zinc and depression rating scores in depressed patients (Nowak et al 2005), the elderly (Marcellini et al 2006) and postpartum women (Wojcik et al 2006). In addition to this, zinc supplementation produces antidepressant-like effects in animal tests and models such as the forced swim test and can augment the action of orthodox antidepressants in these scenarios (Nowak et al 2005). Theories regarding zinc's aetiological role in depression centre on its inhibition of *N*-methyl D-aspartate receptor (NMDA) function and interestingly, suicide victims demonstrate a statistically significant 26% decrease in zinc's antagonistic potency in hippocampal tissue, suggestive of an aberrant interaction between this mineral and the receptor underlying the psychopathology (Nowak et al 2003). Another aspect of interest is the increased inflammatory markers evident in depressed individuals, which would,

through redistribution of zinc, potentially create a pseudo-deficiency (Marcellini et al 2006, Nowak et al 2005).

In spite of growing interest in zinc's antidepressant potential, there has only been one published interventional study to date. Twenty patients with unipolar depression had an improved response to antidepressant medication when taken with zinc aspartate supplements (equivalent to 25 mg elemental daily), according to a small, double-blind pilot study (Nowak et al 2003). Significantly greater reductions in Hamilton Depression Rating Scale scores were achieved with zinc treatment compared to placebo by the 6th week and maintained until the end of the 12-week study.

Diarrhoea

A 2008 Cochrane review of oral zinc treatment for paediatric diarrhoea included 18 trials and 6165 participants (Lazzerini & Ronfani 2008). Typically, the intervention consisted of 10 mg/day of zinc, as either a sulfate, acetate or gluconate salt, administered in a single or divided dose over 2 weeks to children aged 1 month to 5 years presenting with acute or persistent diarrhoea or dysentery. Zinc supplementation consistently reduced the duration and volume of diarrhoea within a few days and while zinc-treated children were significantly more likely to experience vomiting, it was concluded that the benefits of the treatment outweighed this side effect. It is important to note that all except three of these trials were conducted in countries considered to be at high risk of widespread zinc deficiency and in such instances the WHO and UNICEF recommend 10–20 mg/day. This review found no benefit in children less than 6 months old.

Crohn's disease

Although reduced zinc status has been associated with chronic diarrhoea and Crohn's disease (Sturniolo et al 1980), the results from a small open study demonstrated that oral zinc sulfate (110 mg three times daily) resolved intestinal permeability problems in people with increased permeability and decreases relapse rates (Sturniolo et al 2001).

Herpes simplex

In vitro studies confirm that zinc can inhibit the replication of the herpes simplex virus; however, the concentration required is much higher than possible in a physiological context (Overbeck et al 2008). Accordingly, topical preparations have been the most consistently studied with positive results. Overall, application of zinc preparations greatly reduces or eliminates recurrence of genital herpes infections and resolves symptoms of herpes simplex infections (Finnerty 1986, Kneist et al 1995). Zinc sulfate gel applied every 2 h was a more effective treatment than placebo in herpes simplex labialis in a double-blind study of 80 subjects (Kneist et al 1995). Another study of 200 volunteers with herpes simplex found that 0.25% zinc sulfate solution, started within 24 h of lesion appearance and applied 8–10 times daily, cleared lesions within 3–6 days (Finnerty 1986). A randomised, placebo-controlled study using a weak zinc solution (0.05% or 0.025% zinc sulfate) found no effects on frequency, duration or severity of herpes attacks, suggesting that stronger concentrations are required for effectiveness (Graham et al 1985).

Anorexia nervosa

There is evidence that suggests zinc deficiency may be intimately involved with anorexia nervosa, if not as an initiating cause, then as an accelerating or 'sustaining' factor for abnormal eating behaviours that may deepen the pathology of the anorexia in relation to neurological, immunological and metabolic aberrations (McClain et al 1992, Saito et al 2007, Shay & Mangian 2000). Zinc status is compromised in anorexia nervosa due to an inadequate zinc intake, with supplementation (50 mg elemental zinc/day) shown to decrease depression and anxiety, stop body weight loss and improve weight gain (Katz et al 1987, Safai-Kutti 1990). According to one randomised, double-blind, placebo-controlled trial, 100 mg of zinc gluconate (14 mg/day elemental) doubled the rate of subjects with anorexia nervosa increasing their BMI compared to placebo (Birmingham et al 1994). Accordingly, some key researchers advocate for routine prescribing of zinc for a minimum of 2 months in all anorexia nervosa patients (Birmingham & Gritzner 2006).

Improves taste perception

Dysfunctional taste perception, or dysgeusia, is a condition that can at the least affect quality of life (QOL) and occasionally can become life threatening. Research into the aetiology of taste impairment has revealed a long list of possible causes and contributing factors that includes various pathologies and drugs (Brown & Toma 1986, Deems et al 1991, Ikeda et al 2005, Kettaneh et al 2005, Osaki et al 1996, Rareshide & Amedee 1989, Zverev 2004). The pioneer of research in zinc-related taste acuity, Henkin, concluded in 1976 that zinc could not explain all cases of taste impairment (Henkin et al 1976). A subsequent review concurred: 'depletion of zinc can lead to decreased taste acuity but decreased taste acuity is not necessarily associated with depletion of zinc' (Catalanotto 1978).

Impaired gustatory function in the elderly is also well established (Bales et al 1986, Bartoshuk 1989, Deems et al 1991, Greger 1977, Greger & Geissler 1978, Ikeda et al 2005, Kettaneh et al 2005, Sandstead et al 1982, Schiffman 1983), particularly in relation to salt perception (Bales et al 1986, Greger & Sickles 1979, Sandstead et al 1982). Although zinc status also characteristically declines with age (Bales et al 1986, Greger 1977, Greger & Geissler 1978, Sandstead et al 1982), many studies have failed to demonstrate a consistent correlation between the two phenomena. While this has been challenged by the findings of a study (Stewart-Knox et al 2005), previous large-scale studies of elderly patients presenting with hypogeusia or ageusia have indicated that zinc deficiency represents the sole cause in <40% of elderly patients (Deems et al 1991, Ikeda et al 2005). Other major causes of taste impairment in this age group include the effect

of medications and systemic diseases (Deems et al 1991, Ikeda et al 2005, Schiffman 1983). Consequently, confirmation of zinc deficiency in patients with taste impairment is necessary in order to determine the suitability of zinc as a treatment.

Several interventional studies investigating zinc as a treatment for taste impairment have produced generally positive findings. Zinc supplementation of 140 mg of zinc gluconate (20 mg/day elemental) in 50 patients with idiopathic dysgeusia improved gustatory function when compared with placebo (Heckmann et al 2005). In another study of 109 patients with idiopathic taste impairment, including some with low-serum zinc, subjects were randomly assigned to either placebo or one of three zinc treatment groups: 17 mg/day, 34 mg/day or 68 mg/day zinc carnosine for 12 weeks (Sakagami et al 2008). Only those patients receiving 68 mg/day demonstrated significantly improved gustatory sensitivity over placebo. Two studies focussing specifically on improving taste perception in the elderly (Ikeda et al 2008, Stewart-Knox et al 2008) have been successful, particularly in relation to increased salt sensitivity and in one study achieved a 74% response rate for improved gustatory function generally.

In contrast treatment with zinc sulfate (45 mg three times daily) concomitant with and 1 month following radiotherapy treatment in patients suffering from head and neck cancers did not prevent taste alterations typically associated with this treatment and previously speculatively linked with poor zinc status (Halyard et al 2007).

Tinnitus

In addition to its many diverse neurological roles, zinc has specifically been shown to modulate synaptic function in the cochlear nucleus through its involvement with glutamate receptors (Coehlo et al 2007). Also required for production of Cu/Zn SOD, the most abundant antioxidant enzyme in this tissue, zinc has a critical role in its healthy function through control of oxidation and the large amounts of generated reactive oxygen species. There is also evidence that a deficiency of Cu/Zn SOD potentiates ear hair cell degeneration secondary to excessive oxidation damage.

In 1987, a report was published suggesting a link between reduced zinc status and intermittent head noises in people suffering with tinnitus (Gersdorff et al 1987). This has been further investigated in several studies; however, the poorly defined patient groups and use of serum zinc as the means of measuring zinc status makes interpretation of results difficult to assess (Coehlo et al 2007). Results from these studies, however, suggest a non-significant trend of lower serum zinc values for patients suffering this condition compared to healthy controls.

In 1991 Paaske et al reported the results of a randomised, double-blind study of 48 patients with tinnitus that had failed to find a significant effect on symptoms with sustained-release zinc sulfate tablets. Of note, only one subject had low serum zinc levels. A study of 111 subjects aged 20–59 years found that individuals with tinnitus who had normal hearing had significantly lower serum zinc levels than controls, whereas zinc levels were normal for those with accompanying hearing loss (Ochi et al 2003). In addition, a significant correlation between average hearing sensitivity and serum zinc level was observed. Yetiser et al (2002) investigated serum zinc levels and response to supplementation in 40 patients with severe tinnitus of various origins. Some relief in tinnitus symptoms was reported by 57.5% of all subjects who received 220 mg of zinc daily for 2 months; however, the effect was considered minor. When results were divided by age, a different finding emerged as 82% of people over 50 years of age experienced an improvement on the tinnitus scale compared to only 48% of younger subjects. There was no correlation between severity of tinnitus and serum zinc levels. Zinc supplementation (50 mg/day) was further studied in a randomised, placebo-controlled trial involving 41 Turkish patients with tinnitus of no known cause. Active treatment for 2 months produced clinically favourable progress in 46.4% of subjects; however, this result was not statistically significant (Arda et al 2003). A review of these studies concluded that, although hampered by methodological weaknesses, zinc treatment may be beneficial in some tinnitus sufferers and while an optimal dose for zinc has yet to be elucidated, most successful designs have employed 50–66 mg/day of elemental zinc in divided doses (Coehlo et al 2007).

Warts

Oral zinc sulfate (10 mg/kg) supplements administered in three divided doses per day (up to 600 mg/day) for 2 months completely cleared recalcitrant viral warts in 87% of patients, according to a single-blind, placebo-controlled trial of 80 volunteers with at least 15 viral warts that were resistant to other treatments (Al Gurairi et al 2002). Warts were completed cleared in 61% of patients after 1 month of treatment, whereas none of the patients receiving placebo reported a successful response and some developed new warts. In both placebo and treatment groups, the drop-out rates were high: 50% and 45%, respectively. Interestingly, patients in the treatment group with low-serum zinc baseline levels (mean 62.4 microgram/100 mL) exhibited no signs or symptoms of deficiency and zinc serum levels failed to rise in the patients who remained resistant to zinc therapy. Treatment with high-dose zinc supplements was accompanied by nausea and in some cases vomiting and mild epigastric pain, although these symptoms were described as mild and transient.

OTHER USES

Reducing the risk of cancer

Epidemiological studies suggest that zinc deficiency may be associated with increased risk of cancer (Prasad & Kucuk 2002).

HIV and AIDS

Given zinc deficiency most profoundly compromises T-cell function, interest in zinc treatment for HIV and AIDS has been ongoing. Low plasma zinc

concentration occurs in HIV infection, especially with advancing illness (Wellinghausen et al 2000). The balance of evidence favours the view that a low plasma zinc level is a marker for disease progression (Siberry et al 2002). A series of small interventional studies have produced mixed results, some demonstrating improved immune markers and reduced opportunistic infections (Mocchegiani et al 1995, Zazzo et al 1989), while others suggest either no therapeutic effect or increased risk of progression from HIV to AIDS (Tang et al 1996). These contrasting findings have been speculatively attributed to differences in baseline zinc status amongst subjects. One author points out that anti-retroviral treatment has been shown to counteract zinc deficiency and therefore administering zinc to individuals taking this medication may enhance the risk of zinc toxicity and its associated immune impairment (Overbeck et al 2008). Large intervention trials are not available to determine whether zinc supplementation in HIV infection produces positive outcomes.

Malaria

Duggan et al (2005) identified low plasma zinc levels in children with acute malaria, including a significant correlation between evidence of illness severity, CRP levels and zinc status; however, this may be an artifact of the acute phase effects on zinc homoestasis, rather than indicative of genuine depletion (Overbeck et al 2008). Zinc supplementation (10 mg elemental) randomly allocated to preschool children residing in a malaria-endemic region of Papua New Guinea for 6 days a week over 46 weeks reduced morbidity due to *Plasmodium falciparum* (Shankar et al 2000). Further studies have produced contradictory findings in relation to zinc's capacity to prevent malaria while studies of treatment regimen that include zinc as an adjuvant to standard chemotherapy have found no benefit (Overbeck et al 2008).

Pneumonia

A randomised, placebo-controlled trial in which 1665 children aged less than 12 months were given 70 mg of zinc prophylactically found a reduced incidence of pneumonia (17%), with severe pneumonia incidence reducing by 49%. It also reduced upper respiratory tract infection (URTI) by 8% and reactive airways disease (bronchiolitis) by 12% (Brooks et al 2005). Serum zinc concentrations have been shown to be negatively correlated with pneumonia incidence in a study of nursing home residents, prompting researchers to consider zinc as a potential prophylactic in this population also; however, there are currently no RCTs (Overbeck et al 2008).

A randomised, controlled trial involving 270 children aged between 6 and 12 months, hospitalised with pneumonia, found that those given 20 mg/day of zinc (as acetate) showed significant reductions in recovery time from severe pneumonia. Overall hospital stay duration was also reduced when used with standard antimicrobial therapy (Brooks et al 2004). Results from a similarly designed study, however, failed to corroborate zinc as an effective treatment (Bose et al 2006). The results of Coles et al may help to clarify these disparate findings (2007). While investigating the efficacy of adjunctive zinc treatment (10 mg zinc sulfate administered twice daily) in paediatric patients (<2 years) hospitalised for severe pneumonia, the researchers differentiated between bacterial and non-bacterial aetiologies. In doing so, it became apparent that zinc supplementation in bacterial pneumonia detrimentally affected recovery prolonging hospital stays, etc — an effect not seen in the non-bacterial cases. This may be explained by the negation of the acute phase response's sequestering of zinc in the liver and gives weight to the argument that zinc supplementation should be avoided in such scenarios, as increased availability of this mineral to the pathogen may facilitate its growth and replication (Calder 2002)

Wilson's disease

Patients with diagnosed Wilson's disease have increased hepatic glutathione and reduced oxidation when supplemented with zinc sulfate (220 mg three times daily) for 3 months, compared with those using penicillamine (Farinati et al 2003).

Alzheimer's dementia

Cognitive performance was temporarily improved after 3 months of zinc supplementation (zinc chelate 15 mg) taken twice daily by six subjects with Alzheimer's disease (Potocnik et al 1997). Although the initial improvement was not maintained in this small open study, a modest cognitive improvement on psychometric testing was observed at 12 months for the four patients evaluated.

DOSAGE RANGE

Australian RDI

Children
- 1–3 years: 3 mg/day.
- 4–8 years: 4 mg/day.
- 9–13 years: 6 mg/day.
- Males 14–18 years: 13 mg/day.
- Females 14–18 years: 7 mg/day.

Adults
- Males >19 years: 14 mg/day.
- Females >19 years: 8 mg/day.

Pregnancy
- <19 years: 10 mg/day.
- ≥19 years: 11 mg/day.

Deficiency
- 25–50 mg elemental zinc daily.

According to clinical studies

- Common cold — zinc gluconate lozenges (free of sorbitol, mannitol or citric acid).
  - Adults: 9–24 mg elemental zinc dissolved in the mouth, without chewing every 2 hours for acute treatment.

  - School-aged children: dissolved in the mouth once daily as prophylaxis and four times daily for acute treatment.
    It is recommended that citrus fruits or juices be avoided 30 minutes before or after dissolving each lozenge to avoid negating the effects of zinc.
- Improved immune function in elderly — 45 mg/day elemental zinc as zinc gluconate.
- Common cold — nasal gel spray containing either 33 mmol/L zincum gluconicum administered four times a day for a maximum of 10 days.
- Pneumonia — 70 mg/day prophylactically or 20 mg/day in children suffering acute infection. Malaria — 10 mg/day elemental zinc.
- ARMD — zinc oxide (equivalent to 80 mg elemental zinc), together with 500 mg vitamin C, 400 IU vitamin E and 15 mg beta-carotene, taken daily or 50 mg/day of zinc as zinc monocysteine as stand-alone treatment.
- ADHD — 55–150 mg zinc sulfate daily.
- T1DM— 30 mg/day (type of zinc unknown).
- T2DM – 50 mg/day zinc acetate.
- Wound healing — 2.5 mg/kg zinc sulfate daily, zinc oxide form preferable, topically.
- Leg ulcers — 600 mg zinc sulfate daily.
- Male fertility — 60 mg/day of zinc sulfate and 5 mg/day as folic acid.
- Acne vulgaris — 90–200 mg (50 mg elemental) daily.
- Crohn's disease — 110 mg zinc sulfate taken three times daily.
- Diarrhoea — 10–20 mg/day elemental zinc in children <5 years for 2 weeks.
- Herpes infection — 0.25% zinc sulfate solution applied 8–10 times daily.
- Anorexia nervosa — 14–50 mg elemental zinc daily.
- Dysgeusia — 20 mg/day elemental zinc as zinc gluconate and 68 mg/day as zinc carnosine.
- Tinnitus — 50–200 mg daily of zinc (salt unknown).
- Warts — 10 mg/kg zinc sulfate taken orally in three divided doses (up to 600 mg/day) for 1–2 months.

TOXICITY

Signs of toxicity are nausea, vomiting, diarrhoea, fever and lethargy and have been observed after ingestion of 4–8 g zinc according to a 2002 WHO report. Single doses of 225–450 mg of zinc usually induce vomiting (King 2003).

Doses of zinc ranging from 100 to 150 mg/day interfere with copper metabolism and cause hypocuprinaemia, red blood cell microcytosis and neutropenia if used long term.

ADVERSE REACTIONS

Mild gastrointestinal distress has been reported at doses of 50–150 mg/day of supplemental zinc (King 2003). According to a randomised, double-blind study, zinc gluconate glycine lozenge (104 mg equivalent to 13.3 mg ionic zinc) taken every 3–4 h is well tolerated (Silk & LeFante 2005). Of the side effects that were reported, dry mouth and a burning sensation on the tongue were probably related to use, whereas symptoms of nausea, dizziness, lightheadedness and upset stomach were considered as possibly related.

SIGNIFICANT INTERACTIONS

Calcium

High levels of dietary calcium impair zinc absorption in animals, but it is uncertain whether this occurs in humans — separate doses by 2 h.

Captopril and enalopril

These drugs increase urinary excretion of zinc (Golik et al 1990). Monitor for signs and symptoms of zinc deficiency. Increased zinc intake may be required with long-term drug treatment.

Coffee

Coffee reduces zinc absorption — separate intakes by 2 h (Pecoud et al 1975).

Copper

High zinc intakes (100–150 mg/day) interfere with copper metabolism and can cause hypocuprinaemia with long-term use. Avoid using high-dose zinc supplements long term, or increase intake of copper.

Folate

Folate intake may reduce zinc levels — observe patient for signs and symptoms of zinc deficiency with long-term folate supplementation.

Iron

Supplemental (38–65 mg/day elemental) iron decreases zinc absorption (King 2003) — separate doses by 2 h.

Non-steroidal anti-inflammatory drugs (NSAIDs)

Zinc interacts with NSAIDs by forming complexes with these drugs (Dendrinou-Samara et al 1998) — separate dose by 2 h.

Tetracyclines and quinolones

Complex formation between zinc and tetracycline results in reduced absorption of both substances with potentially reduction in efficacy — separate dose by 2 h.

Thiazide and loop diuretics

These diuretics increase urinary zinc loss — monitor for signs and symptoms of zinc deficiency with long-term drug use. Increased zinc intake may be required with long-term therapy.

Methylphenidate

The efficacy of this drug is improved by supplementation with zinc sulfate (15 mg elemental zinc) for 6 weeks in children with ADHD. There is no change to side effects reported (Akhondzadeh et al 2004).

Vaccinations

Zinc acetate improved seroconversion of vibriocidal antibodies in children given a cholera vaccination (Albert et al 2003) in both faecal and serum titres (Karlsen et al 2003).

Radiotherapy
Radiotherapy reduces plasma zinc levels (Ertekin et al 2004). Supplementation may be required with intensive radiotherapy treatment.

Interferon-alpha/ribavirin
Interferon-alpha and ribavirin treatment for hepatitis C patients is not affected by zinc supplementation (Ko et al 2005).

Orlistat
Orlistat has no significant effect on zinc levels (Zhi et al 2003).

Tricyclic antidepressants and selective serotonin reuptake inhibitors
Zinc supplementation (25 mg elemental zinc daily) improves the efficacy of antidepressants such as tricyclic antidepressants and SSRIs after 2 weeks of intervention (Nowak et al 2003) — beneficial interaction possible.

CONTRAINDICATIONS AND PRECAUTIONS
Amiloride reduces zinc excretion and can lead to zinc accumulation (Reyes et al 1983). Therefore, supplementation should be used with caution.

PREGNANCY USE
Zinc is safe in pregnancy and may improve fetal heart rate in zinc-deficient mothers (in conjunction with iron and folic acid) (Merialdi et al 2004).

PRACTICE POINTS/PATIENT COUNSELLING
- Zinc is involved in many chemical reactions that are important for normal body functioning and it is essential for health and wellbeing.
- Although zinc supplements are traditionally used to treat deficiency, they are also used to prevent deficiency in conditions associated with low zinc status or deficiency, such as acrodermatitis enteropathica, anorexia nervosa, malabsorption syndromes, conditions associated with chronic diarrhoea, alcoholism, diabetes, HIV and AIDS, recurrent infections, severe burns, Wilson's disease and sickle cell anaemia.
- Zinc supplements are also popular among athletes in order to counteract zinc loss that occurs through perspiration.
- Zinc lozenges have been used to prevent and treat the symptoms of the common cold and oral supplements have been used to treat acne vulgaris, improve wound healing and chronic leg ulcers, resolve intestinal permeability problems and reduce recurrences in Crohn's disease, treat recalcitrant warts, reduce symptoms of tinnitus and improve ADHD.
- Topical applications of zinc have been used to treat acne vulgaris (in combination with erythromycin), herpes simplex and to promote wound healing.
- Numerous interactions exist between other minerals, foods and medicines and zinc.

PATIENTS' FAQs
What will this supplement do for me?
Zinc is found in every cell of the body and is essential for health and wellbeing. Some studies have found that supplements are not only useful to treat and prevent deficiency, but may also be useful in conditions such as the common cold, poor wound healing and leg ulcers, diabetes, Crohn's disease, acne vulgaris, warts, ADHD and tinnitus. Topical preparations may be useful in acne vulgaris (with erythromycin), herpes infection and chronic wounds.

When will it start to work?
This depends on the indication (refer to monograph for more details).

Are there any safety issues?
Used in high doses, zinc can cause nausea, vomiting, gastrointestinal discomfort and, if used long term, reduce copper levels. Zinc also interacts with a number of other minerals, foods and medicines.

APPENDIX 1

GLOSSARY AND ABBREVIATIONS

Abortifacient – Substance used to terminate a pregnancy.
ACE – angiotensin-converting enzyme
ACM – all-cause mortality
ACTH – adrenocorticotropic hormone
Active constituents – Chemical components that exhibit pharmacological activity and contribute to the agent's overall therapeutic effects.
Acute – Beginning abruptly; sharp and intense; subsiding after a short period.
Adaptogen – Innocuous agent, non-specifically increasing resistance to physical, chemical, environmental, emotional or biological factors ('stressors') and having a normalising effect independent of the nature of the pathological state.
ADHD – attention deficit hyperactivity disorder
ADI – acceptable daily intake
Adjuvant – Substance added to a mixture to enhance the effect of the main ingredient.
ADR – adverse drug reaction
ADRAC – Adverse Drug Reactions Advisory Committee (Australia)
Adverse reaction – Unintended harmful, undesirable or seriously unpleasant response to a medicine at doses intended for prophylaxis, diagnosis or therapeutic effect.
Aerial parts – All parts of a plant that are above the ground. Very often, plants that have useful aerial parts are harvested when flowering (e.g. St John's wort — *Hypericum perforatum* of the Hypericaceae family).
Agonist – Substance that binds to and activates a receptor, thereby causing a response.
Alkaloid – Naturally occurring cyclic organic compound containing nitrogen in a negative oxidation state, which has limited distribution in living organisms. Based on their structures, alkaloids are divided into several subgroups: non-heterocyclic alkaloids and heterocyclic alkaloids, which are again divided into 12 major groups according to their basic ring structure. They tend to have marked physiological effects in vivo (e.g. morphine, codeine, nicotine).
Allostatic responses – Changes that occur in the body in order to adapt and respond to physical or psychological change (e.g. standing, sitting, stress). They are critical to survival, have broad boundaries and involve the sympathetic nervous system and the hypothalamus–pituitary–adrenal axis.
ALT – alanine aminotransferase
Amino acid – Organic compound composed of one or more basic amino groups and one or more acidic carboxyl groups; form the basic structural units of protein.
AMP – adenosine monophosphate
Analgesic – Substance that relieves the symptoms of pain.
ANF – atrial natriuretic factor
Antagonist – Substance that binds to a receptor (blocking others from doing so), but does not activate it, causing a diminished response.
Anthelmintic – Substance that destroys or assists in the expulsion of intestinal worms.
Anthocyanins – Compounds responsible for the bright colours of most flowers and fruits; water-soluble pigments that occur as glycosides and their aglycones (anthocyanidins) and have significant antioxidant activity.
Anti-allergic – Substance that reduces the allergic response (e.g. antihistamine activity or mast-cell stabilisation).
Anti-asthmatic – Substance that prevents asthma attacks and/or reduces their severity.
Anti-emetic – Substance or procedure that prevents or alleviates nausea and vomiting.
Anticholinergic – Agent that blocks cholinergic receptors (e.g. atropine), which results in inhibition of transmission of parasympathetic nerve impulses.
Anticoagulant – Substance that prevents or delays blood coagulation (e.g. warfarin).
Antidiabetic – Substance that aids in blood glucose management or improves management of diabetes via other mechanisms.
Antigen – Substance that the body recognises as foreign and to which it can evoke an immune response; often it is a protein.
Antimicrobial – Substance that kills microorganisms or inhibits their growth or replication.
Antioxidant – Substance that inhibits or delays the oxidation of a second substance; also described as scavenging free-radical molecules.

Antiplatelet – Substance that inhibits platelet aggregation and thereby prolongs bleeding time (e.g. aspirin).
Antipruritic – Substance or procedure that relieves or prevents itching.
Antipyretic – Substance or procedure that reduces fever.
Antispasmodic – Substance that reduces smooth muscle spasms.
Antitussive – Substance that suppresses the cough reflex.
Anxiolytic – Substance used to treat and relieve anxiety states.
Apolipoprotein – Protein on the surface of lipoproteins that may bind to receptors, activate enzymes involved in lipoprotein metabolism and provide structure.
Apoptosis – Programmed cell death.
ARMD – age-related macular degeneration
AST – aspartate aminotransferase
Astringent – Substance that precipitates proteins, causes vasoconstriction and constriction of mucous membranes, and reduces cell permeability when applied topically.
ATP – adenosine triphosphate
Bark – Outermost protective layer of a tree trunk, formed by layers of living cells just above the wood itself. There are usually high concentrations of the active ingredients in the bark (e.g. cinnamon from *Cinnamomum camphora* of the Lauraceae family).
Bioavailability – Proportion of an administered dose that reaches the systemic circulation intact.
Bitter tonic – Herbs with a bitter taste, which are used to stimulate the upper gastrointestinal tract (i.e. stomach, liver, pancreas). They stimulate appetite and digestive function.
BMD – bone mineral density
BMI – body mass index
BPH – benign prostatic hypertrophy
Bulb – Fleshy structure made up of numerous layers of bulb scales, which are leaf bases. Bulbs that are popular for medicinal use include onion and garlic (*Allium cepa* and *A. sativum*, respectively, both of the Liliaceae family).
BZM – bortezomib
CAM – complementary and alternative medicine
Cardioprotective – Substance that protects the heart from damage by toxins or ischaemia (oxygen deficiency).
Carminative – Substance that relieves flatulence, abdominal distension, spasm and discomfort by relaxing the intestinal muscles and sphincters.
Carotenoid – Group of red, yellow or orange highly unsaturated pigments found naturally in foods. Some are converted to vitamin A in the body and most exhibit antioxidant properties.
CFS – chronic fatigue syndrome
Chelation – Chemical interaction of a metal ion with another substance, which results in the formation of a molecular complex with the metal firmly bound and isolated.
Chemoprevention – Substance or intervention that reduces the incidence of cancer.
Cholagogue – Substance that stimulates the release of stored bile from the gall bladder.
Choleretic – Substance that stimulates both the production and the flow of bile.
Chronic – Persisting for a long period of time.
Chylomicrons – Large particles that transport dietary cholesterol and fatty acids from the gastrointestinal tract to the liver.
CMEC – Complementary Medicines Evaluation Committee
CMs – complementary medicines
CNS – central nervous system
Cognitive activator – Substance or procedure that stimulates the mental processes such as memory, judgment, reasoning and comprehension.
Cohort study – Study concerning a specific population that shares a common characteristic (e.g. same age, same gender).
Cold extraction – Process in which plant material is extracted in a solvent of differing polarity at room temperature, which enables maximum extraction of most components.
Contraindication – Any factor that makes it undesirable or dangerous to administer a medicine or perform a procedure on a specific patient.
Corticosteroids – Steroidal hormones that are synthesised and released from the adrenal cortex; includes both glucocorticoids and mineralocorticoids.
COX – cyclo-oxygenase
CPI – consumer product information
CRP – C-reactive protein
Crude herb – Raw plant before it is processed or dried.
CVD – cardiovascular disease
Cytochrome P450 (CYP) – Proteins involved in extra-mitochondrial electron transfer, chiefly in the liver and during detoxification. There are many CYPs; they are named by the root symbol CYP, followed by a number for family, a letter for subfamily, and another number for the specific gene.
DBP – diastolic blood pressure
Debridement – Removal of foreign objects, damaged tissue, cellular debris and dirt from a wound or burn to prevent infection and promote healing.
Decoction – Aqueous medicine made from an extract of water-soluble substances, usually with the aid of boiling water.
Decongestant – Substance or procedure that reduces or eliminates congestion and swelling, usually of mucous membranes.
Demulcent – Substance that soothes and reduces irritation of tissues such as skin or mucous membranes.
DHA – docosahexanoic acid
DHEA – dehydroepiandrosterone
Diuretic – Substance that modifies kidney function to increase the rate of urine flow.
DMBA – 7,12-dimethylbenz[a]anthracene
Double-blind study – Study in which neither the test subject nor the clinician knows whether a placebo or active medicine is being administered. The substances are often identifiable by a code that is revealed

after results are obtained. This method is widely used in clinical studies to confer greater objectivity.
DSM-IV–*Diagnostic and Statistical Manual [of Mental Health Disorders]*, 4th edn.
EAR–estimated average requirement
EBM–evidence-based medicine
ECG–electrocardiogram
EEG–electroencephalogram
EGCG–epigallocatechin-3-gallate
Emmenagogue–Substance that increases the strength and frequency of uterine contractions, and initiates and promotes menstrual flow (some are also abortifacients).
Emollient–Substance that softens tissue and reduces irritation, usually of the skin and mucous membranes.
Endogenous–Originating from within the body; synthesised by the body.
Epidemiological study–Study of occurrence and distribution of disease in large human populations.
Ergogenic aid–Substance that improves energy utilisation with the expectation that it will enhance physical performance.
Erythropoiesis–Process of erythrocyte production in the bone marrow.
ESADDI–estimated safe and adequate daily dietary intake
ESCOP–European Scientific Cooperative on Phytotherapy
ESR–erythrocyte sedimentation rate
Essential amino acids–Eight amino acids that are required for health and must be obtained from the diet: isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan and valine.
Essential fatty acids (EFA)–Polyunsaturated acids that are required for growth and general health and must be obtained from the diet (e.g. omega 3 EFAs found in fish oils).
Essential oil–Volatile oils usually extracted from plants through a process of either steam distillation or microwave extraction. They consist of terpenes (mono- and sesquiterpenoids and coumarins) and are of considerable importance as active ingredients (e.g. peppermint oil from *Mentha* × *piperita* from the Lamiaceae family).
Expectorant–Substance that promotes the expulsion of mucus, fluids or sputum from the respiratory tract.
Extract–Substance prepared by the use of solvents or evaporation to separate it from the original material.
Fatty oils–Non-volatile, insoluble oils pressed from either the seeds or the fruits of a plant (e.g. olive oil).
FDA–Food and Drug Administration (USA)
FEV_1–forced expiratory volume in 1 second
Flavonoids–Compounds responsible for the colour of flowers, fruits and sometimes leaves. The name derives from the Latin *flavus*, meaning yellow. Some may contribute to the colour as co-pigment. Flavonoids protect the plant from UV damage and play a role in reproduction by attracting pollinators.
Flowers–Commonly used in medicine (e.g. cloves (*Syzygium aromaticum*, Myrtaceae family), chamomile (*Chamomilla recutita*, Asteraceae family) and marigold (*Calendula officinalis*, Asteraceae family)).
Fluid extract–Hydro-ethanolic extract of crude herbal material with a drug solvent ratio of 1:1 or 1:2 (e.g. 1 part herb to 1 or 2 parts solvent).
Free radical–Unstable organic compound with at least one unpaired electron.
Fresh plant tincture–Herbal extract made from fresh plant instead of dried material.
Fruit–Most commonly used seeds are anis (*Pimpinella anisum*) and fennel (*Foeniculum vulgare*), both of the Apiaceae family. In some instances, the fruit peel is used specifically (e.g. citrus spp, from the Rutaceae family).
FSH–follicle stimulating hormone
FVC–forced vital capacity
GABA–gamma-aminobutyric acid
GAD–generalised anxiety disorder
Galactogogue–Substance that promotes the production and flow of breast milk.
GI–glycaemic index
GLUT–glucose transporters
Glycoside–Sugar-containing compound with a glycone (sugar) and aglycone (non-sugar) components that can be cleaved on hydrolysis.
GSH–glutathione
Gum–Solids consisting of mixtures of polysaccharides that are water-soluble and are partially digested by humans. Gums sometimes flow from a damaged plant stem as a defence mechanism or sometimes as a protective system against the invasion of bacteria and fungi. Well-known examples are gum arabic (*Acacia senegal*, Leguminosae), and aloe gel (*Aloe vera*, Liliaceae family: gum mixed with water).
Gy–gray (unit of radiation)
Haemostasis–Physiological process that stops bleeding (i.e. vessel constriction, platelet plug formation and blood coagulation).
HbA_{1c}–haemoglobin A_{1c}
HBeAg–hepatitis B early antigen
HDL–high-density lipoprotein
Hepatoprotective–Substance that reduces or prevents liver damage; protects against the destructive effect of hepatotoxins.
High-performance liquid chromatography–Very popular and widely used method for the analysis and isolation of bioactive natural products.
HIV–human immunodeficiency virus
HMG-CoA–3-hydroxy-3-methylglutaryl coenzyme A
HPA–hypothalamus–pituitary–adrenal [axis]
HRT–hormone replacement therapy
HSV–herpes simplex virus
Hypnotic–Substance that induces sleep or the feeling of dreamy sleepiness.
Hypoglycaemic–Substance that reduces blood glucose levels.
Hypolipidaemic–Substance that reduces blood levels of lipids (e.g. cholesterol, triglycerides).
Iatrogenic–Condition caused by medical or surgical treatment or diagnostic procedures.
IBS–irritable bowel syndrome
IFN–interferon
Ig–immunoglobulin

IL–interleukin
IM–integrative medicine
Immunomodulation–Substance that alters the immune response; also described as having a balancing effect on immune responses.
Immunostimulant–Substance that augments the immune response.
Immunosuppressant–Substance that inhibits the immune response.
Infused oil–Herbal extract using a fixed oil as the solvent.
Infusion (herbal)–Herbal tea prepared by pouring boiling water over plant parts and steeping for a short time.
iNOS–inducible nitric oxide synthase
Inotrope–Substance that has an effect on the force of myocardial contractility. A positive inotrope increases the force of contraction whereas a negative inotrope decreases the force of contraction.
INR–international normalised ratio
Interaction–Pharmacological interaction is said to occur when the response to one medicine varies from what is usually predicted because another substance has altered the response. An interaction may lead to drug toxicity or a loss of drug effect; however, it can also be manipulated to benefit the patient by improving outcomes, reducing side effects or reducing drug dose and costs.
IO–integrative oncology
IP–intraperitoneal
IQ–intelligence quotient
Ischaemia–Oxygen deficiency.
IV–intravenous
IVF–in vitro fertilisation
Laxative–Substance that causes bowel evacuation.
LD_{50}–median lethal dose
LDL–low-density lipoprotein
LH–luteinising hormone
LOHAS–lifestyles of health and sustainability
Maceration–Method of herbal extraction in which cut herb is soaked in solvent (such as cold water) for a period of time before draining, straining and pressing.
Meta-analysis–Quantitative statistical procedure for combining the results of independent studies to better analyse the efficacy of a specific treatment.
Mineral–Compound containing a non-metal, metal, radical or phosphate required for proper body functioning and health maintenance.
Mineral oil–Faecal softener and laxative.
MND–motor neuron disease
MOA–monoamine oxidase
MRL–maximum residue level
MRSA–methicillin-resistant *Staphylococcus aureus*
MSSA–methicillin-sensitive *Staphylococcus aureus*
MTHFR–methylenetetrahydrofolate reductase
Mucilage–Sticky mixture of carbohydrates produced by plant cell activity. Herbs with a high mucilaginous content are often used as demulcents (e.g. *Ulmus fulvus* (slippery elm), *Althea officinalis* (marshmallow)).
Mucolytic–Substance that dissolves or destroys mucus.
Myocardial infarction (MI)–Necrosis (death) of a portion of the heart muscle; also called a heart attack.
NAD–nicotinamide adenine dinucleotide
NADPH–nicotinamide adenine dinucleotide phosphate
Narrow therapeutic index (NTI)–The dose required to produce a toxic effect in 50% of test animals (TD_{50}) is close to the dose required to produce an effective therapeutic response in 50% of test animals (ED_{50}); NTI drugs are particularly susceptible to adverse interactions (e.g. digoxin).
Nervine–Substance that exerts a relaxant effect; described as nourishing and strengthening the nervous system.
Neurotransmitter–Chemical that acts as a messenger, enabling transmission of nerve impulses across synapses and neuromuscular junctions. The most important are acetylcholine, catecholamines (noradrenaline, adrenaline and dopamine), serotonin, some amino acids and neuro-active peptides.
NK–natural killer [cell]
NO–nitric oxide
NSAID–non-steroidal anti-inflammatory drug
Nutritive–Substance that contains numerous nutrients such as vitamins, minerals, carbohydrates and fats.
NYHA–New York Heart Association [classification]
OA–osteoarthritis
OCP–oral contraceptive pill
OS–oxygen species
OTC–over-the-counter
Oxytocic–Substance that exerts similar effects to oxytocin (i.e. stimulates smooth muscle, usually of the uterus, to contract).
P-glycoprotein (P-gp)–P-gp is a transport protein found on the surface of hepatocytes, renal tubular epithelial cells, epithelial cells in the intestine, and placenta and capillary epithelial cells in the brain. It has a counter-transport activity (i.e. can transport medicines from the blood back into the gastrointestinal tract, thereby reducing bioavailability).
PCOS–polycystic ovaries syndrome
PEF–peak expiratory flow
Peri-operative–Pertaining to the time of surgery.
PG–prostaglandin
Pharmacodynamics–Study of the effects of drugs on living organisms.
Pharmacokinetics–Study of the actions of drugs within the body (i.e. absorption, distribution, metabolism and excretion, onset of action and duration of effect).
Phytochemical–Naturally occurring chemical found in a plant.
Phytotherapy–Study and application of plant medicine; a modern term used to describe scientifically investigated and validated herbal medicine.
Placebo–Harmless inactive substance that does not contain an active medicine; used in clinical studies for comparison with medicines suspected of exerting a clinical effect to determine whether in fact a significant response does occur.
PMS–premenstrual syndrome

PO–per os (oral)
Polypharmacy–Use of many medicines by a patient with one or more health conditions.
Polysaccharide–Carbohydrate polymer formed from three or more sugar molecules.
Postprandial–After a meal.
Poultice–Paste made from crushed fresh plant, either mixed with oil or alcohol or simply made in water and applied to the parts of the body.
PPI–proton-pump inhibitors
ppm–parts per million
Prospective study–Study designed to determine the relationship between a condition and a characteristic shared by some members of a group. Usually the population selected is healthy at the beginning of the study and is observed over a period of time for the development of certain conditions in the different subgroups (e.g. smokers and non-smokers).
PTH–parathyroid hormone
PUFA–polyunsaturated fatty acid
PUVA–psoralen ultraviolet A
QOL–quality of life
RA–rheumatoid arthritis
RAST–radioallergosorbent test
RCT–randomised controlled trial
RDA–recommended daily allowance
RDI–recommended daily intake
Resin–Excreted from specialised cells or ducts in plants, this consists of a mixture of essential oils and polymerised terpenes; usually insoluble in water. Well-known examples include frankincense (*Boswellia sacra*) and myrrh (*Commiphora molmol*), both of the Burseraceae family
Restorative–Restores or renews a person's state of health or consciousness to normal.
Rhizome–Root; underground fleshy stem that grows horizontally and acts as food storage for the plant.
Risk factor–Factor that increases a person's susceptibility to an unwanted, unpleasant or unhealthy event or disease.
Root–Fleshy or woody, usually underground, part of a plant; may be fibrous (e.g. *Urtica dioica* or *U. radix* of the Urticaceae family, stinging nettle), solid (e.g. *Glycyrrhiza glabra* of the Leguminosae family, licorice) or fleshy (e.g. *Harpagophytum procumbens* of the Pedaliaceae family, devil's claw).
ROS–reactive oxygen species
Salicylate–Substance that contains or is derived from salicylic acid.
Saponin–Vast group of glycosides that occur in many plants; dissolve in water and form a soapy solution when shaken; used in demulcents.
SBP–systolic blood pressure
SC–subcutaneous
Seeds–Contained in the fruit and used medicinally (e.g. fennel seed, *Foeniculum vulgare*: Apiaceae).
SLE–systemic lupus erythematosus
SSRI–selective serotonin reuptake inhibitor
SVCT–sodium vitamin C co-transporters
Synergistic–Several components acting or working together in a coordinated manner to produce an effect greater than that of the sum of the individual effects.
Tannin–Substance that forms a precipitate with proteins, nitrogenous bases, polysaccharides and some alkaloids and glycosides (e.g. *Camellia sinensis*, the herb commonly used to make 'tea', is a rich source of tannins).
TCM–traditional Chinese medicine
TGA–Therapeutic Goods Administration (Australia)
Th–T helper cell
Therapeutic index–Measure of the safety of a medicine based upon the dose required to produce a toxic effect in 50% of test animals (TD_{50}) divided by the dose required to produce an effective therapeutic response in 50% of test animals (ED_{50}); i.e. $TI = TD_{50}/ED_{50}$.
Thin layer chromatography–Analytical method using glass or aluminium plates precoated with the sorbent (e.g. silica gel) to separate a compound mixture according to the polarity of its components.
Tincture–Hydro-ethanolic extraction of crude herbal material; usually extracted in the ratio of 1:5 (1 part herb to 5 parts solvent). Glyceride tinctures may be prepared by using glycerol rather than alcohol.
TNF–tumour necrosis factor
TPN–total parenteral nutrition
TSH–thyroid stimulating hormone
URTI–upper respiratory tract infection
UTI–urinary tract infection
UV–ultraviolet
VAS–visual analogue scale
VDR–vitamin D receptors
Vitamin–Organic compound essential to life. With few exceptions, vitamins cannot be synthesised in the body and must be obtained from the diet.
VLDL–very low-density lipoprotein
WOMAC–Western Ontario and McMasters University Osteoarthritis Index
WSR–whole systems research

APPENDIX 2

HERB/NUTRIENT–DRUG INTERACTIONS

NOTES

Assumptions

The following assumptions were made when collating and assessing information for this table:

- Information has been compiled from the monographs included in this book.
- The clinical significance of many interactions is still unknown because controlled trials are lacking in most cases. In these instances, interactions are based on evidence of pharmacological activity and case reports, and have a sound theoretical basis, although remain to be tested.
- All information refers to oral dose forms unless otherwise specified.
- Information is correct at the time of writing; however, because of the ever-expanding knowledge base developing in this area, new research is constantly being published.
- The interaction table is provided as a guide only and should not replace the use of professional judgment. It has been developed to assist clinicians when advising patients.

Using this guide in practice

- Refer to Chapter 8 (Interactions with herbal and natural medicines) for background information.
- Commonly used prescription and over-the-counter medications are organised by therapeutic class and subclass and are listed alphabetically.
- Common names have been used when referring to herbs.
- Refer to the original monograph for more information about a particular substance.

Recommendations

Avoid — There may be insufficient information available to be able to advise using the two substances safely together, so avoid until more is known. The drug may have a narrow therapeutic index and there is sufficient evidence to suggest that the interaction may be clinically significant. Consider an alternative treatment that is unlikely to produce an undesirable interaction.

Avoid use unless under medical supervision — Harmful effects of the potential interaction can be avoided if doses are altered appropriately under professional supervision or the patient is closely monitored. Some of these interactions can be manipulated to the advantage of the patient. Changes to the dosage regimen may be required for safe combined use.

Exercise caution — The possibility exists of an interaction that may change effects clinically; be aware and monitor. It is prudent to tell patients to be aware and seek advice if they are concerned.

Observe — Interaction may not be clinically significant at the usual recommended doses and may be theoretical; however, the clinician should be alert to the possibility of an interaction.

Beneficial interaction possible — Prescribing the interacting substance may improve clinical outcomes; for example, reducing drug requirements, complementing drug effects, reducing drug side effects, counteracting nutritional deficiencies caused by drugs, alleviating drug withdrawal symptoms and enhancing patient wellbeing.

Key to the table by herb/supplement

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
ALLERGIC DISORDERS				
Antihistamines				
Antihistamines and mast-cell-stabilising drugs	Albizia	Has additive effects.	Beneficial interaction possible.	Both in vitro and in vivo tests have reported significant mast-cell-stabilisation effects similar to those of cromoglycate — clinical significance unknown.
	Baical skullcap	Additive effects.	Beneficial interaction possible.	Luteolin and baicalein have been shown to inhibit IgE antibody-mediated immediate- and late-phase allergic reactions in mice — clinical significance unknown.
	Perilla	Additive effects.	Observe — drug dose may need modification.	Perilla seed extract has been shown to inhibit histamine release from mast cells in a dose-dependent manner — clinical significance unknown
ANALGESIA				
Narcotic analgesics				
Codeine	Adhatoda	Additive effects.	Beneficial interaction possible.	Theoretically will increase antitussive effects of drug.
	Kava kava	Additive effects.	Exercise caution.	Increased CNS depression theoretically possible.
Morphine	Kava kava	Additive effects.	Exercise caution — may be beneficial under professional supervision.	Increased CNS depression theoretically possible.
	Tyrosine	Additive effects.	Observe — potential beneficial interaction under professional supervision.	Tyrosine potentiates morphine-induced analgesia by 154% in mice.
	Withania	Reduced morphine tolerance/dependence.	Beneficial interaction possible with professional supervision.	In animal studies, repeated administration of withania (100 mg/kg) inhibited morphine tolerance and dependence, so it is sometimes used in opiate withdrawal.
Simple analgesics and antipyretics				
Simple analgesics and antipyretics	Meadowsweet	Additive effects.	Observe — beneficial interaction possible.	Additive anti-inflammatory and analgesic effects theoretically possible.
	Vitamin E	Additive effects.	Beneficial interaction possible. Drug dosage may require modification.	Vitamin E may enhance the pain-modifying effects of drug in RA.
	Willowbark	Additive effects.	Observe — beneficial interaction possible.	Additive anti-inflammatory and analgesic effects theoretically possible.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Aspirin	Andrographis	Increased bruising and bleeding.	Observe.	Herb inhibits platelet aggregation, observed in animal and clinical studies.
	Bilberry	Increased bruising and bleeding.	Exercise caution with high-dose (> 170 mg) anthocyanadins unless under medical supervision.	Dose is extremely high and not relevant to clinical practice.
	Evening primrose oil	Increased bruising and bleeding.	Observe, although beneficial interaction possible.	Theoretically concomitant use may enhance anti-inflammatory and antiplatelet effects — clinical significance unknown.
	Feverfew	Increased bruising and bleeding.	Interaction unlikely but observe.	Feverfew inhibits platelet aggregation in vitro and in vivo, no effects were seen in clinical study; however, contradictory evidence exists.
	Fish oils	Additive effects.	Observe — beneficial interaction possible.	No haemorrhagic effects were seen in a clinical study — theoretical concern only if increased bruising or bleeding. Pharmacological activity of fish oils may have benefits for some patients taking aspirin for CVD prevention or for its anti-inflammatory properties.
	Garlic	Increased bruising and bleeding.	Interaction unlikely at usual doses. Observe when using higher doses (> 7 g).	Theoretically, a pharmacodynamic interaction is possible when using garlic at high doses (> 7 g) in excess of usual dietary amounts; however, results from clinical studies cast doubt on this proposition.
	Ginger	Increased bruising and bleeding.	Interaction unlikely at usual doses. Exercise caution at high dose (> 10 g) unless under professional supervision.	Inhibits platelet aggregation at very high doses — dietary intake appears safe.
	Ginkgo biloba	Increased bruising and bleeding.	Interaction unlikely.	Pharmacodynamic interaction theoretically possible because of platelet-activating-factor inhibitor activity; however, clinical trials show no significant change to bleeding or platelet activity, so interaction unlikely to be significant.
	Grapeseed extract	Increased bruising and bleeding.	Observe.	Theoretically may enhance antiplatelet activity and anti-inflammatory activity of aspirin and may increase risk of bleeding.
	Guarana	Increased bruising and bleeding.	Observe.	Theoretically possible as in vitro and in vivo research has identified antiplatelet activity — clinical significance unknown.
	Meadowsweet	Increased bruising and bleeding.	Observe — beneficial interaction possible.	Theoretically may enhance anti-inflammatory and antiplatelet effects.
	Myrrh	Increased bruising and bleeding.	Observe with myrrh preparations. Exercise caution with guggul preparations.	Guggul inhibited platelet aggregation in vitro and in a clinical study, so concurrent use may theoretically increase the risk of bleeding — implications for *Commiphora molmol* use unclear.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Policosanol	Increased bruising and bleeding.	Observe.	Doses > 10 mg/day may inhibit platelet aggregation.
	Turmeric	Increased bruising and bleeding.	Observe with concentrated extracts.	Curcumin inhibits platelet aggregation in vitro and in vivo — clinical significance is unclear and likely to be dose dependent.
	Vitamin C	Decreased vitamin C effects.	Observe.	Aspirin may interfere with both absorption and cellular uptake mechanisms for vitamin C, thereby increasing vitamin C requirements, as observed in animal and human studies. Increased vitamin C intake may be required with long-term therapy.
	Willowbark	Increased bruising and bleeding.	Exercise caution with high dose (> 240 mg/day).	Theoretically may enhance anti-inflammatory and antiplatelet effects. Although a clinical study found that consumption of salicin 240 mg/day produced minimal effects on platelet aggregation, higher doses may have a significant effect.
Paracetamol	Andrographis	Reduced side effects.	Beneficial interaction possible	Andrographis may exert hepatoprotective activity against liver damage induced by paracetamol.
	Garlic	Reduced side effects.	Beneficial interaction possible.	Garlic may exert hepatoprotective activity against liver damage induced by paracetamol.
	Quercetin	Reduced side effects.	Beneficial interaction possible.	Quercetin may exert hepatoprotective activity against liver damage induced by paracetamol.
	St Mary's thistle	Reduced side effects.	Beneficial interaction possible under professional supervision.	St Mary's thistle may exert hepatoprotective activity against liver damage induced by paracetamol.
	SAMe	Reduced side effects.	Beneficial interaction possible.	SAMe may exert hepatoprotective activity against liver damage induced by paracetamol.
	Schisandra	Reduced side effects.	Beneficial interaction possible.	Schisandra may exert hepatoprotective activity against liver damage induced by paracetamol.
CARDIOVASCULAR SYSTEM				
Anti-angina agents				
Nitroglycerin/glyceryl trinitrate (e.g. anginine)	Arginine	Additive hypotensive effects.	Caution.	Theoretically, additive vasodilation and hypotensive effects may occur.
	Vitamin E	Prevention of drug tolerance.	Beneficial interaction possible.	Oral vitamin E prevented nitrate tolerance when given concurrently with transdermal nitroglycerin (10 mg/24 h) according to one randomised placebo-controlled study

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Anti-impotence				
Phosphodiesterase-5 Inhibitor (e.g. Sildenafil)	Arginine	Additive effects.	Exercise caution.	Theoretically, additive vasodilation and hypotensive effects may occur.
Anti-arrhythmic agents				
	Astragalus	Additive effects.	Observe.	Additive effects are theoretically possible with IV administration of astragalus, based on positive inotropic activity identified in clinical studies; the clinical significance of these findings for oral dose forms is unknown.
	Devil's claw	Additive effects.	Observe.	Devil's claw has demonstrated anti-arrhythmic activity, but interaction is theoretical and clinical significance is unclear.
	Hawthorn	Additive effects.	Observe.	Hawthorn has demonstrated anti-arrhythmic activity in vitro and in vivo, but interaction is theoretical and clinical significance is unclear.
	Magnesium	Additive effects.	Observe.	High-dose oral magnesium has demonstrated anti-arrhythmic activity according to one clinical trial.
Amiodarone	Vitamin B_6 (pyridoxine)	Increased drug side effects.	Exercise caution.	Vitamin B_6 may increase risk of drug-induced photosensitivity.
Anticoagulants, antiplatelets Monitor bleeding time and signs and symptoms of excessive bleeding				
Anticoagulants (e.g. warfarin)	Andrographis	Increased bruising and bleeding.	Exercise caution — monitor bleeding time.	Andrographolide and other constituents of andrographis are clinically confirmed to inhibit platelet-activating-factor-induced platelet aggregation.
	Baical skullcap	Increased risk of bruising and bleeding.	Exercise caution.	Baical flavonoids have been shown to inhibit platelet aggregation in vitro — clinical significance unknown.
	L-Carnitine	Increased bruising and bleeding.	Observe.	According to one case report, L-carnitine 1 g/day may potentiate the anticoagulant effects of acenocoumarol. Further investigation required to confirm interaction.
	Celery	Increased bruising and bleeding.	Observe with high dose extracts.	Although celery contains naturally occurring coumarins, interaction is unlikely.
	Chamomile	Increased bruising and bleeding.	Observe.	According to one case report, internal haemorrhage occurred in elderly patient taking warfarin and topical and oral chamomile preparations. Further investigation required to confirm interaction.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Chondroitin	Increased bruising and bleeding.	Observe.	Theoretical risk; not observed in clinical trials.
	Coenzyme Q10	Reduced drug effects.	Interaction unlikely with standard doses. Observe patients taking high doses.	A double-blind crossover study found that oral CoQ10 100 mg/day had no significant effect on INR or warfarin levels; however, in vivo tests using 10 mg/kg/day CoQ10 decreased serum concentrations of warfarin by increasing drug metabolism.
	Cranberry	Increased bruising and bleeding.	Exercise caution — due to potential seriousness of interaction.	Clinical investigations are conflicting. However a recent study suggests a pharmocodynamic interaction is likely. Monitor INR closely.
	Devil's claw	Increased bruising and bleeding.	Observe until clinical studies can confirm interaction.	Case reports suggest possible anticoagulant activity but most are inconclusive. Further investigation required to confirm interaction.
	Dong quai	Increased bruising and bleeding.	Observe with oral supplements.	A controlled trial using an IV preparation of dong quai found that it prolonged prothrombin times, but it is unknown whether this effect occurs with oral dose forms.
	Evening primrose oil	Increased bruising and bleeding.	Exercise caution — monitor bleeding time, signs and symptoms.	Gamma-linoleic acid in evening primrose oil affects prostaglandin synthesis, leading to inhibition of platelet aggregation — clinical significance is unknown.
	Fenugreek	Increased bruising and bleeding.	Interaction unlikely.	While it contains naturally occurring coumarins, a placebo-controlled study found no effect on platelet aggregation, fibrinogen or fibrinolytic activity.
	Feverfew	Increased bruising and bleeding.	Interaction unlikely. Observe.	Although feverfew inhibits platelet aggregation in vitro and in vivo, no effects were seen in a clinical study.
	Fish oils	Increased bruising and bleeding.	Interaction unlikely at usual therapeutic doses. Exercise caution with very high doses (> 12 g) unless under medical supervision.	A review of clinical studies concluded there was no clinically significant effect on bleeding with usual therapeutic doses. According to one clinical study, bleeding time may be increased at high doses of 12 g/day.
	Garlic	Increased bruising and bleeding.	Interaction unlikely at usual dietary intake. Exercise caution with use of high dose (> 7 g) supplements.	Theoretically, a pharmacodynamic interaction is possible when using garlic at high doses (> 7 g) in excess of usual dietary amounts; however, results from clinical studies cast doubt on this proposition.
	Ginger	Increased bruising and bleeding.	Observe at usual therapeutic doses. Exercise caution at high dose (> 10 g).	Inhibits platelet aggregation at high doses.
	Ginkgo biloba	Increased bruising and bleeding.	Interaction unlikely based on clinical trials. Observe high risk patients — due to potential seriousness of interaction.	Theoretically ginkgo may increase bleeding and there have been several case reports of haemorrhage; however, evidence from clinical studies does not support this. Ginkgo has no effect on pharmacokinetics, pharmacodynamics or clinical effects of warfarin. This is supported by a recent systematic review.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Ginseng — Korean	Possibly increased bruising and bleeding.	Observe.	Two case reports have indicated ginseng reduced antithrombotic effects of warfarin. In vitro and in vivo ginseng has demonstrated inhibition of platelet aggregation; however, a recent open-label study found no effect of ginseng on warfarin in healthy males.
	Ginseng — Siberian	Increased bruising and bleeding.	Observe.	In vivo study demonstrated that an isolated constituent in Siberian ginseng has anticoagulant activity and a clinical trial found a reduction in blood coagulation induced by intensive training in athletes — whether these effects also occur in non-athletes is unknown. A recent combination study of Siberian ginseng, andrographis and warfarin produced no significant effects on drug pharmacokinetics and pharmacodynamics.
	Glucosamine		Exercise caution until interaction can be confirmed.	Case reports suggest a possible interaction with warfarin.
	Goji	Increased bruising and bleeding.	Exercise caution until interaction confirmed clinically.	Two case reports of interaction between goji and warfarin producing altered INR. Further investigation required to confirm interaction.
	Grapeseed extract	Increased bruising and bleeding.	Exercise caution until interaction confirmed clinically.	Inhibits platelet aggregation in vitro and ex vivo — clinical significance unknown.
	Green tea	Reduced drug effects.	Exercise caution with high doses.	A case report of excessive intake (2.25–4.5 L green tea daily) was reported to inhibit warfarin activity and decrease INR. Further investigation required to confirm interaction.
	Guarana	Increased bruising and bleeding.	Exercise caution until interaction confirmed clinically.	In vitro and in vivo research has identified antiplatelet activity — clinical significance unknown.
	Horseradish	Increased bruising and bleeding risk.	Interaction unlikely.	Although it contains coumarins, interaction unlikely.
	Licorice	Increased bruising and bleeding.	Exercise caution until interaction confirmed clinically.	Isoliquiritigenin inhibits platelet aggregation, and glycyrrhizin inhibits prothrombin, according to in vitro and in vivo tests — clinical significance unknown.
	Meadowsweet	Increased bruising and bleeding.	Observe until interaction confirmed clinically.	In vitro tests have indicated anticoagulant activity — clinical significance unknown.
	Myrrh	Increased bruising and bleeding.	Observe with myrrh preparations. Exercise caution with guggul preparations.	Guggul inhibited platelet aggregation in vitro and in a clinical study, so concurrent use may theoretically increase the risk of bleeding — implications for *Commiphora molmol* use unclear.
	Policosanol	Increased bruising and bleeding.	Exercise caution with doses > 10 mg daily.	Current evidence is contradictory, as one study failed to detect an interaction between policosanol and warfarin, but others have found that doses > 10 mg/day may inhibit platelet aggregation.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Psyllium	Decreased drug absorption.	Separate doses by at least 1 hour.	
	Red clover	Increased bruising and bleeding.	Interaction unlikely.	Theoretically, coumarin content could exert anticoagulant activity; however, dicoumarol produced by microorganisms in poorly dried sweet clover has established anticoagulant effects. Interaction unlikely from extracts prepared from properly dried red clover.
	Rosemary	Increased bruising and bleeding.	Exercise caution with concentrated extracts until interaction confirmed clinically.	Rosemary demonstrates antithrombotic activity in vitro and in vivo — clinical significance unknown.
	St John's wort (unlikely to relate to low-hyperforin-containing products)	Decreased drug effects.	Exercise caution — monitor for signs of reduced drug effectiveness and adjust dose if necessary. Prothrombin time or INR should be closely monitored with addition or withdrawal of St John's wort.	Metabolism of warfarin is chiefly by CYP2C9, and a minor metabolic pathway is CYP3A4, so theoretically it may interact with St John's wort. A clinical study found no change to INR or platelet aggregation (Jiang et al 2004), but there are case reports suggesting St John's wort may lower the INR.
	Slippery elm	Decreased drug absorption.	Separate doses by at least 2 hours.	Theoretical interaction — clinical significance unknown.
	Turmeric	Increased bruising and bleeding.	Exercise caution with concentrated extracts until interaction confirmed clinically.	Curcumin inhibits platelet aggregation in vitro and in vivo — concomitant use with high dose turmeric may theoretically increase risk of bleeding.
	Vitamin E	Increased bruising and bleeding.	Exercise caution with high-dose supplements (> 1000 IU daily). Until clinical significance can be established, prothrombin time or INR should be closely monitored with addition or withdrawal of high-dose vitamin E supplements.	Clinical studies have produced conflicting results: several found no effects of platelet aggregation or coagulation, although others found an increased bleeding risk. Clinical study of 1200 IU/d for 28 days had no effects on platelet aggregation; another of 900 IU/d for 12 weeks did not alter coagulation activity. Alternatively 50 mg/d increased gingival bleeding. Overall, it appears people with reduced levels of vitamin K may be more susceptible to the effects of vitamin E potentiating warfarin activity.
	Willow bark	Increased bruising and bleeding.	Exercise caution with high dose (> 240 mg/day).	Theoretically, may enhance anti-inflammatory and antiplatelet effects. Although a clinical study found that consumption of salicin 240 mg/day produced minimal effects on platelet aggregation, higher doses may have a significant effect.
Antiplatelet drugs (e.g. aspirin)	Andrographis	Increased bruising and bleeding.	Observe.	Herb inhibits platelet aggregation, observed in animal and clinical studies.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Bilberry	Increased bruising and bleeding.	Exercise caution with high-dose (> 170 mg) anthocyanadins unless under medical supervision.	Dose is extremely high and not relevant to clinical practice.
	Evening primrose oil	Increased bruising and bleeding.	Observe, although beneficial interaction possible.	Theoretically, concomitant use may enhance anti-inflammatory and antiplatelet effects — clinical significance unknown.
	Feverfew	Increased bruising and bleeding.	Observe.	Feverfew inhibits platelet aggregation in vitro and in vivo; no effects were seen in clinical study; however, contradictory evidence exists.
	Fish oils	Additive effects.	Observe — beneficial interaction possible.	No haemorrhagic effects were seen in a clinical study — theoretical concern. Pharmacological activity of fish oils may have benefits for some patients taking aspirin for CVD prevention or for its anti-inflammatory properties.
	Garlic	Increased bruising and bleeding.	Interaction unlikely.	Theoretically, may enhance platelet aggregation. Recent clinical investigation found garlic had no effect on platelet function.
	Ginger	Increased bruising and bleeding.	Interaction unlikely at standard intake. Exercise caution at high dose (> 10 g) unless under professional supervision.	Inhibits platelet aggregation at very high doses.
	Ginkgo biloba	Increased bruising and bleeding.	Interaction unlikely.	Theoretically possible because of platelet-activating-factor inhibitor activity. There are rare case reports of haemorrhage and haematoma; however, clinical trials show no significant change to bleeding or platelet activity. This is confirmed in a recent systematic review.
	Grapeseed extract	Increased bruising and bleeding.	Observe.	Theoretically, may enhance antiplatelet activity.
	Guarana	Increased bruising and bleeding.	Observe.	Theoretically possible, as in vitro and in vivo research has identified antiplatelet activity — clinical significance unknown.
	Meadowsweet	Increased bruising and bleeding.	Observe — beneficial interaction possible.	Theoretically may enhance anti-inflammatory and antiplatelet effects.
	Myrrh	Increased bruising and bleeding.	Observe with myrrh preparations. Exercise caution with guggul preparations.	Guggul inhibited platelet aggregation in vitro and in a clinical study, so concurrent use may theoretically increase the risk of bleeding — implications for *Commiphora molmol* use unclear.
	Policosanol	Increased bruising and bleeding.	Observe.	Doses > 10 mg/day may inhibit platelet aggregation.
	Turmeric	Increased bruising and bleeding.	Observe with concentrated extracts.	Curcumin inhibits platelet aggregation in vitro and in vivo — clinical significance is unclear and likely to be dose dependent.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Vitamin C	Decreased vitamin C effects.	Observe.	Aspirin may interfere with both absorption and cellular uptake mechanisms for vitamin C, thereby increasing vitamin C requirements, as observed in animal and human studies. Increased vitamin C intake may be required with long-term therapy.
	Willow bark	Increased bruising and bleeding.	Interaction unlikely at usual doses. Exercise caution with high dose (> 240 mg/day)	Theoretically, may enhance anti-inflammatory and antiplatelet effects. Although a clinical study found that consumption of salicin 240 mg/day produced minimal effects on platelet aggregation, higher doses may have a significant effect.
Antihypertensive agents				
Antihypertensive drugs	Arginine	Additive hypotensive effects.	Exercise caution.	Theoretical concern.
	Essential fatty acids — omega-3 and omega-6	Increased drug effects.	Observe — beneficial interaction possible.	Both omega-3 and omega-6 fatty acids exhibit mild antihypertensive activity.
	Evening primrose oil	Additive effects.	Observe — monitor drug requirements (interaction may be beneficial).	Evening primrose oil has been shown to enhance the effects of several antihypertensive drugs, including dihydralazine, clonidine and captopril in rats under experimental conditions.
	Garlic	Additive effects.	Observe — beneficial interaction possible.	Clinical trials have shown garlic to reduce blood pressure, which may lead to reduced drug requirements.
	Hawthorn	Additive effects.	Observe — beneficial interaction possible.	Mild antihypertensive activity has been reported with long-term use of hawthorn, which may lead to reduced drug requirements.
	Licorice	Reduced drug effect.	Exercise caution — monitor blood pressure when high-dose licorice preparations are taken for more than 2 weeks.	High-dose glycyrrhizin taken long-term can lead to increased blood pressure.
	Oats (oat-based cereals)	Additive effects.	Observe — monitor drug requirements (interaction may be beneficial).	A clinical trial has shown that ingestion of oat-based cereals decreased blood pressure in 73% of hypertensive patients and reduced drug requirements. Patients taking oats, oat milk and oat bran should be monitored.
	Olive leaf and olive oil	Additive effects.	Possible beneficial interaction possible under professional supervision.	Theoretical, as hypotensive effects have been observed with olive oil and olive leaf extracts.
	Stinging nettle	Additive effects.	Observe.	Additive effects are theoretically possible.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Hydralazine (e.g. Apresoline, Alphapress)	Coenzyme Q10	Reduced CoQ10 serum levels.	Beneficial interaction possible.	Increased CoQ10 intake may be required with long-term therapy.
	Vitamin B_6 (pyridoxine)	Reduced vitamin B_6 absorption.	Separate doses by at least 2 hours.	A clinical trial has shown that the drug may induce B_6 deficiency, so increased intake may be required with long-term therapy.
Methyldopa (e.g. Aldomet)	Coenzyme Q10	Reduced CoQ10 serum levels.	Beneficial interaction possible.	Increased CoQ10 intake may be required with long-term therapy.
ACE inhibitors (e.g. captopril, enalapril)	Iron	Reduced drug effect.	Separate doses by at least 2 hours.	Reduced absorption of ACE inhibitors. A small clinical trial found that concomitant iron administration reduced area-under-the-curve plasma levels of unconjugated captopril by 37%.
	Zinc	Reduced zinc levels.	Monitor for zinc efficacy and zinc status.	These drugs increase urinary excretion of zinc. Increased zinc intake may be required with long-term therapy.
Verapamil	St John's wort	Reduces drug levels via increased metabolism.	Monitor and adjust dose as necessary.	Decreases drug serum levels via CYP induction.
Beta-adrenergic-blocking agents	Coenzyme Q10	Reduced CoQ10 serum levels.	Beneficial interaction possible.	Increased CoQ10 intake may be required with long-term therapy.
	Calcium	Reduced drug effects.	Separate doses by at least 2 hours.	Simultaneous use can reduce both agents. Separate doses by 2 hours.
Propranolol	Myrrh	Reduced drug effect.	Observe.	A clinical trial has shown that guggulipid reduces bioavailability of propranolol. It is uncertain what implications this has for use of *Commiphora molmol.*
	Vitamin E	Reduced drug effect.	Observe.	According to in vitro research, vitamin E inhibits drug uptake in human cultured fibroblasts — clinical significance unknown.
Calcium-channel blockers (e.g. verapamil)	Calcium	Reduced drug effect.	Avoid high-dose supplements unless under medical supervision.	Calcium may reduce antihypertensive effect of drug.
	Magnesium	Additive effects.	Observe — monitor drug requirements (interaction may be beneficial).	A meta-analysis of 20 randomised trials showed that magnesium has a modest antihypertensive activity and may enhance the activity of calcium-channel blockers.
	Vitamin D	Reduced drug effect.	Exercise caution unless under medical supervision.	Vitamin D may reduce effectiveness of these drugs.
Felodipine	Peppermint oil	Increased drug effects.	Exercise caution.	Peppermint oil has been shown to increase the oral bioavailability of felodipine in animal studies.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Nifedipine	Ginseng — Korean	Increased drug effects.	Exercise caution.	
	St John's wort	Reduced drug effect.	Monitor for signs of reduced drug effectiveness — adjust dose where necessary.	St John's wort has been shown to induce nifedipine metabolism.
Diltiazem	Myrrh	Reduced drug effect.	Observe.	A clinical trial has shown that guggulipid reduces bioavailability of diltiazem. It is uncertain what implications this has for use of *Commiphora molmol*.
	Quercetin	Increased drug effects.	Exercise caution under professional supervision; drug dose may need adjustment.	Increased drug bioavailability observed in vivo — clinical significance unknown.
Antimigraine preparations				
Antimigraine preparations	Coenzyme Q10	Additive effects.	Beneficial interaction possible.	CoQ10 demonstrated migraine-prevention activity in a clinical study.
	Feverfew	Additive effects.	Beneficial interaction possible.	Feverfew demonstrated migraine-prevention activity in several clinical studies.
	Vitamin B_2 (riboflavin)	Additive effects.	Beneficial interaction possible.	Vitamin B_2 has demonstrated migraine-prevention activity in several clinical studies.
Clonidine (e.g. Catapres)	Coenzyme Q10	Reduced CoQ10 serum levels.	Beneficial interaction possible.	In vivo study indicates that clonidine reduces serum CoQ10 levels. Increased CoQ10 intake may be required with long-term therapy.
Cardiac inotropic agents				
Cardiac glycosides	Calcium	Additive effects.	Exercise caution.	Concurrent use of high-dose calcium can act synergistically and may induce arrhythmias and potentiate their toxicity.
	Hawthorn	Additive effects.	Exercise caution — monitor drug requirements (interaction may be beneficial).	Theoretical interaction, as in vitro and in vivo studies indicate that hawthorn has positive inotropic activity. Small clinical study found interaction not clinically significant when digoxin 0.25 mg taken with hawthorn (WS1442) 450 mg twice daily.
	Psyllium	Reduced drug absorption.	Separate doses by at least 1 hour.	Soluble fibre may decrease the bioavailability of cardiac glycosides.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Digoxin (e.g. Lanoxin) Adverse effects of high-dose digoxin include: nausea, vomiting, diarrhoea, confusion, fainting, palpitations, irregular heartbeat, visual disturbances.	Aloe vera	Increased drug toxicity.	Avoid long-term use of high-dose preparations.	Long-term oral use of aloe can deplete potassium levels and reduced potassium status lowers the threshold for drug toxicity.
	Ginseng — Korean	Interferes with therapeutic drug monitoring for digoxin.	Exercise caution — drug assay may produce false positive and negative results.	There are no confirmed clinical case reports of actual interaction.
	Guarana	Increased drug toxicity.	Avoid long-term use of high-dose preparations.	Long-term guarana use can deplete potassium levels and reduced potassium status lowers the threshold for drug toxicity.
	Licorice	Increased drug toxicity.	Avoid long-term use of high-dose preparations (> 100 mg glycyrrhizin daily > 2 weeks) unless under medical supervision.	Long-term use of licorice can induce hypokalaemia, which can increase sensitivity to cardiac glycoside drugs, thereby reducing the threshold for drug toxicity. One case report exists of digitalis toxicity in an elderly man taking licorice-containing Chinese herbal laxative.
	Quercetin	Increased drug toxicity.	Avoid concurrent use owing to seriousness of interaction.	Increased drug bioavailability possible, observed by in vivo study.
	St John's wort	Reduced drug effects.	Avoid unless under medical supervision. Monitor for signs of reduced drug effectiveness and adjust dose if necessary. When St John's wort is started or ceased, monitor serum levels and alter drug dosage as required.	St John's wort induces CYP enzymes and P-glycoprotein. A clinical trial shows that St John's wort significantly decreases serum levels of drug within 10 days of concomitant use. More recently herb drug interaction was found to be clinically significant.
	Slippery elm	Decreased drug absorption.	Separate doses by at least 2 hours.	Theoretical interaction — clinical significance unknown.
	Withania	Interferes with therapeutic drug monitoring for digoxin.	Exercise caution — drug assays may be modestly altered.	

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Diuretics				
Diuretics	Dandelion leaf	Additive effects.	Observe.	Theoretically, increased diuresis is possible — clinical significance is unknown.
	Elder	Additive effects.	Observe.	Theoretically, increased diuresis is possible with concomitant use; clinical significance is unknown.
	Green tea	Additive effects.	Observe.	Theoretically, increased diuresis possible owing to caffeine content of herb — clinical significance is unknown.
	Guarana	Additive diuretic effects but decreased hypotensive effects of drug.	Exercise caution. Monitor potassium status.	Theoretically, increased diuresis and decreased hypotensive effects are possible — clinical significance is unknown.
	Licorice	Increased potassium excretion.	Avoid long-term use unless under medical supervision. Monitor potassium status.	Potassium loss may become significant when licorice is used in high doses (> 100 mg glycyrrhizin daily) for longer than 2 weeks.
Loop diuretics	Magnesium	Increased magnesium excretion.	Monitor magnesium efficacy and status — beneficial interaction possible.	Increased magnesium intake may be required with long-term therapy.
	Stinging nettle	Additive effects.	Observe.	Theoretically, increased diuresis is possible — clinical significance is unknown.
	Vitamin B_1 (thiamin)	Reduced B_1 levels.	Monitor B_1 efficacy and status — beneficial interaction possible.	Chronic use may result in lowered vitamin status. Increase intake of vitamin B_1-containing foods or consider long-term supplementation.
	Zinc	Increased urinary zinc excretion.	Monitor zinc efficacy and status — beneficial interaction possible.	Increased zinc intake may be required with long-term therapy.
Potassium-sparing diuretics	Magnesium	Increased magnesium effects.	Observe.	
Thiazide diuretics	Calcium	Decreased urinary calcium excretion.	Observe. Monitor serum calcium and look for signs of hypercalcaemia.	
	Magnesium	Increased magnesium excretion.	Monitor magnesium efficacy and status — beneficial interaction possible.	Increased magnesium intake may be required with long-term therapy.
	Zinc	Increased urinary zinc excretion.	Monitor zinc efficacy and status — beneficial interaction possible.	Increased zinc intake may be required with long-term therapy.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Hydrochlorothiazide (e.g. Diclotride)	Coenzyme Q10	Reduced CoQ10 serum levels.	Beneficial interaction possible.	Increased CoQ10 intake may be required with long-term therapy.
	Vitamin B_{12} (cobalamin)	Reduces drug-induced hyper-homocysteinaemia.	Beneficial interaction possible in conjunction with folate.	Hydrochlorothiazide may increase homocysteine levels.
Hypolipidaemic agents				
Hypolipidaemic agents	Chromium	Additive effects.	Observe. Monitor drug requirements — interaction may be beneficial.	Clinical trials indicate that chromium reduces total cholesterol levels.
	Evening primrose oil	Additive effects.	Observe — interaction may be beneficial.	Several animal studies have demonstrated EPO's lipid-lowering effects — clinical significance unknown.
	Fenugreek	Additive effects.	Observe. Monitor drug requirements — interaction may be beneficial.	Clinical trials indicate that fenugreek exerts a lipid-lowering activity in diabetics with elevated lipids.
	Garlic	Additive effects.	Observe. Monitor drug requirements — interaction may be beneficial.	A meta-analysis of 13 clinical trials concluded that garlic significantly reduces total cholesterol levels — effects are described as modest.
	Myrrh	Additive effects.	Observe. Monitor drug requirements — interaction may be beneficial for guggul preparations.	Guggul has demonstrated cholesterol-lowering activity in several clinical studies.
	Oats (oat-based cereals)	Reduced drug absorption. Additive effects.	Separate doses by 2–3 hours. Beneficial interaction possible — monitor drug requirements.	Clinical trials indicate that oat-based cereals reduce total cholesterol levels. However, two case reports exist of a reduced effect of lovastatin in patients taking 50–100 g oat bran daily. This effect is probably due to the fibre content inhibiting the absorption of the drug.
	Policosanol	Additive effects.	Interaction uncertain.	Pharmacodynamic interaction previously thought possible; however, recent clinical studies cast doubt on this.
	Psyllium	Additive effects.	Beneficial interaction possible.	Recent meta-analysis confirmed the capacity of psyllium to exert a time- and dose-dependent cholesterol-lowering effect.
	Red yeast rice	Additive effects.	Observe — beneficial interaction possible. Drug dose may require modification.	Red yeast rice contains low levels of naturally occurring statins, which exert clinically significant lipid-lowering activity.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Vitamin B_3 (niacin)	Additive effects.	Beneficial interaction possible — caution with sustained-release form.	Several clinical trials confirm the cholesterol-lowering activity of niacin and the safety of niacin with statins; however, the sustained-release form may be less safe.
Cholestyramine (e.g. Questran Lite, colestipol [e.g. Colestid])	Fat-soluble vitamins (A, D, E, K, beta-carotene)	Reduced vitamin absorption.	Separate doses by at least 4 hours and monitor vitamin status.	Increased dietary intake may be required or consider vitamin supplementation with long-term therapy.
	Folate	Reduced folate absorption.	Separate doses by at least 4 hours and monitor iron status.	Increased vitamin intake may be required with long-term therapy.
	Iron	Reduced iron absorption.	Separate doses by at least 4 hours and monitor iron status	Investigations have shown that cholestyramine and colestipol bind to iron citrate. Increased iron intake may be required with long-term therapy.
	Lutein and zeaxanthin	Reduced vitamin absorption.		Increased vitamin intake may be required with long-term therapy.
	Lycopene	Reduced vitamin absorption.	Separate doses by at least 2 hours and monitor vitamin status.	Drugs that reduce fat absorption may also reduce lycopene absorption. Increased vitamin intake may be required with long-term therapy.
	Vitamin D	Reduced vitamin absorption.	Separate doses by at least 1 hour prior to or 4–6 hours after drug ingestion.	Such drugs may compromise the absorption of all fat-soluble vitamins.
	Vitamin E	Reduced vitamin absorption.	Separate doses by at least 4 hours and monitor vitamin status.	Increased vitamin intake may be required with long-term therapy.
Chitosan	Vitamin C	May increase cholesterol-lowering effect.	Beneficial interaction possible.	According to preliminary animal study, concomitant use may provide additional benefit in lowering cholesterol.
Fibric-acid derivatives (e.g. gemfibrozil)	Coenzyme Q10	Reduced CoQ10 serum levels.	Beneficial interaction possible — separate doses by 4 hours.	Increased CoQ10 intake may be required with long-term therapy.
	Beta-carotene	Improved drug effects.	Beneficial interaction possible.	In clinical studies, a positive interaction was established between fibrate and beta-carotene, generating significantly increased HDL-cholesterol levels.
HMG-CoA reductase inhibitors (statins)	Carnitine	Additive effects.	Beneficial interaction.	Human studies have demonstrated the addition of L-carnitine to statin therapy lowers serum lipoprotein (a) levels in patients with type 2 diabetes.
	Coenzyme Q10	Reduced CoQ10 serum levels.	Beneficial interaction possible.	Clinical study indicates several statin drugs reduce CoQ10 levels — increased CoQ10 intake may be required with long-term therapy.
	Vitamin A	Increased vitamin A activity.	Observe.	A clinical trial has reported increased serum levels of vitamin A — clinical significance unclear.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Vitamin B_3 (niacin)	Additive effects.	Beneficial interaction possible — caution with sustained-release form.	Several clinical trials confirm the cholesterol-lowering activity of niacin and the safety of niacin with statin; however, the sustained-release form may be less safe.
	Vitamin D	Increased vitamin effects.	Monitor nutrient status	Through unknown mechanisms long-term use of statins is associated with increased 25(OH)D levels — clinical significance is unknown.
Pravastatin (e.g. Pravachol)	Fish oils	Additive effects.	Beneficial interaction possible.	A clinical trial suggests improved lipid-lowering effects when used concurrently. In particular, fish oils will lower triglycerides.
Simvastatin (e.g. Lipex, Zocor)	Peppermint oil	Additive effects.	Observe. Monitor drug requirements — interaction may be beneficial.	Peppermint oil has been shown to increase the oral bioavailability of simvastatin in animal studies — clinical significance unknown.
	St John's wort	Reduced drug effects.	Monitor for signs of reduced drug effectiveness and adjust the dose if necessary.	St John's wort increases metabolism of simvastatin (interaction not expected with pravastatin).
CENTRAL NERVOUS SYSTEM				
Anticonvulsants				
Anticonvulsants	L-Carnitine	Reduced side effects.	Beneficial interaction possible.	L-Carnitine deficiency may cause or potentiate valproic acid toxicity, and supplementation is known to reduce the toxicity of valproate as well as symptoms of fatigue — concurrent use is recommended, as a beneficial interaction is possible.
	Folate	Reduced side effects.	Monitor for drug effectiveness. Beneficial interaction possible.	Requires close supervision to ensure that drug efficacy is not substantially reduced.
	Ginkgo biloba	Reduced drug effects.	Observe.	Based on case reports — further investigation required.
	Psyllium	Reduced drug absorption.	Separate doses by 1–1.5 hours before or after drug.	Absorption of drug concomitantly with psyllium may be delayed.
	St John's wort	Reduced drug effects.	Avoid unless under medical supervision to alter doses appropriately. When St John's wort is started or ceased, monitor serum levels and alter drug dosage as required.	St John's wort may increase drug metabolism, resulting in reduced drug efficacy.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Carbamazepine (e.g. Tegretol) NTI: signs of overdose include CNS and respiratory depression, hypotension, vomiting, fluid retention.	St Mary's thistle	Increased drug effects.	Exercise caution — monitor drug requirements.	May reduce metabolism of drug resulting in increased serum levels and adverse effects (difficult to evaluate evidence).
	Vitamin B_{12} (cobalamin)	Decreased B_{12} levels.	Observe for signs and symptoms of B_{12} deficiency. Beneficial interaction possible.	In studies with children, long-term carbamazepine use led to a decrease in vitamin B_{12} levels. Increased intake may be required with long-term therapy.
Phenobarbitone	Celery	Prolonged action.	Exercise caution.	Celery juice has been found to prolong the action of phenobarbitone in rats — clinical significance unknown.
	Withania	Increased sedation.	Observe, although beneficial interaction possible under professional supervision.	
Phenobarbitone and phenytoin	Kava kava	Increased sedation.	Exercise caution.	
	St John's wort	Decreased drug effects (increased drug metabolism).	Avoid — monitor drug requirements. When St John's wort is started or ceased, monitor serum levels and alter drug dosage as required.	St John's wort may increase drug metabolism, resulting in reduced drug efficacy.
	Vitamin B_{12} (cobalamin)	Increased serum B_{12} levels.	Observe.	One clinical study reported that combined long-term use of phenobarbitone and phenytoin resulted in significantly increased serum B_{12} levels — clinical significance unknown.
Phenytoin	Vitamin B_6 (pyridoxine)	Reduced drug effects.	Exercise caution — monitor for reduced drug effectiveness.	Vitamin B_6 supplements may lower plasma levels and efficacy of drug and decrease seizure control.
	Slippery elm	Decreased drug absorption.	Separate doses by at least 2 hours.	Theoretical interaction — clinical significance unknown.
Phenytoin and valproate	Vitamin D	Reduced nutrient effects.	Beneficial interaction possible.	Anticonvulsants induce catabolism of vitamin D through liver induction — prolonged use is associated with increased risk of developing rickets and osteomalacia; therefore, increased intake may be useful with long-term therapy.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Valproate	Beta-carotene	Reduced nutrient status.	Observe.	Epileptics who gain weight on valproate were found to have reduced plasma concentrations of beta-carotene and other fat-soluble vitamins — which is reversible after valproate withdrawal. Increased intake may be necessary with long-term therapy.
Antidepressants				
Antidepressants including SSRIs, SNRIs, tricyclics and MAOIs	Albizia	Additive effects.	Observe.	Increased risk of serotonergic syndrome is theoretically possible, as the herb increases serotonin levels, according to in vivo studies — clinical significance unknown.
	Ginkgo biloba	Reduced side effects.	Beneficial interaction possible.	Initial open study produced significant improvement in SSRI-induced sexual dysfunction; however, more recent investigations have been inconclusive. Clinical significance difficult to ascertain.
	Lavender	Additive effects.	Observe — beneficial interaction possible.	Lavender may have additive effects.
	St John's wort	Additive effects.	Avoid unless under medical supervision to monitor dose requirements.	Risk of serotonergic syndrome if combined use is not carefully monitored; however, increased antidepressant activity is also possible with appropriate doses.
	SAMe	Additive effects.	Exercise caution.	Theoretically may increase risk of serotonergic syndrome, and a case report exists; however, an experimental study found that brain SAMe levels were significantly reduced after chronic treatment with imipramine, so may be useful adjunctive therapy.
	Tyrosine	Additive effects.	Avoid unless under medical supervision.	Tyrosine is a precursor for several neurotransmitters, which theoretically increases risk of serotonin syndrome.
	Zinc	Improved drug efficacy.	Beneficial interaction possible.	Clinical study has shown 25 mg/d zinc for 2 weeks improves the efficacy of SSRIs and tricyclic antidepressants.
MAOIs	Tyrosine	Increased side effects.	Avoid — unless under medical supervision.	Some tyrosine may be metabolised to tyramine. Concurrent use with MAOIs may lead to hypertensive crisis.
	Rhodiola	Additive effect.	Observe.	Recent in vitro data suggests inhibition of MAO A by rhodiola extracts. A theoretical interaction exists with MAOI antidepressants. Clinical significance as yet unknown.
Tricyclic antide-pressants	Andrographis	Reduced side effects.	Beneficial interaction possible.	Andrographis may exert hepatoprotective activity against liver damage induced by tricyclic antidepressants.
	Coenzyme Q10	Reduced CoQ10 serum levels.	Beneficial interaction possible.	Increased CoQ10 intake may be required with long-term therapy.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	St John's wort (reduction in drug plasma levels)	Additive effects.	Avoid unless under medical supervision.	Although St John's wort decreases drug plasma levels of tricyclic antidepressants, it may increase available serotonin.
	St Mary's thistle	Reduced side effects.	Beneficial interaction possible.	St Mary's thistle may exert hepatoprotective activity against liver damage induced by tricyclic antidepressants.
	Vitamin B_2 (riboflavin)	Reduced nutrient absorption.	Monitor for signs and symptoms of B_2 deficiency — beneficial interaction possible.	Tricyclic antidepressants may reduce the absorption of riboflavin. Increased vitamin B_2 intake may be required with long-term therapy.
Amitriptyline	Vitamin B_2 (riboflavin)	Increased nutrient excretion.	Monitor for signs and symptoms of deficiency.	Amitriptyline has been found to increase the renal excretion of riboflavin. Increased dietary intake may be required with long-term therapy.
Imipramine	Vitamin B_3 (niacin)	Additive effects.	Beneficial interaction possible.	A combination of imipramine with L-tryptophan 6 g/day and niacinamide 1500 mg/day has been shown to be more effective for people with bipolar disorder than imipramine alone.
Lithium	Psyllium	Reduced drug absorption.	Separate dose by 1 hour before or after drug.	Soluble fibre may decrease bioavailability of drug.
	Slippery elm	Decreased drug absorption.	Separate doses by at least 2 hours.	Theoretical interaction — clinical significance unknown.
	Vitamin B_{12} (cobalamin)	Reduced nutrient status.	Monitor B_{12} status.	Lithium administration is shown to decrease serum B_{12} concentrations — clinical significance unclear.
Antipsychotic agents				
Haloperidol (e.g. Serenace)	Ginkgo biloba	Increased drug effects and reduced side effects.	Observe — beneficial interaction possible under professional supervision.	Three clinical trials demonstrate that ginkgo increases drug effectiveness.
	Iron	Reduced iron effect.	Monitor iron status.	May cause decreased blood levels of iron — clinical significance unclear. Increased iron intake may be required with long-term therapy.
	Quercetin	Reduced drug side effects.	Beneficial interaction possible. under professional supervision.	According to in vivo studies, co-administration with quercetin dose-dependently reduced haloperidol-induced chewing movements and tongue protrusions.
	Withania	Reduced drug side effects.	Beneficial interaction possible under professional supervision.	According to in vivo studies, withania is beneficial in the treatment of drug-induced dyskinesia — reduced chewing movements and tongue protrusions possible with concurrent use.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Phenothiazines (e.g. chlorpromazine, trifluoperazine)	Evening primrose oil	Reduced drug effects.	Avoid concomitant use.	Several case reports suggest that evening primrose oil may reduce seizure threshold and reduce drug effectiveness in patients with schizophrenia treated with phenothiazines.
	Coenzyme Q10	Reduced drug-induced side effects.	Beneficial interaction.	Coenzyme Q10 reduces adverse effects of this drug class on CoQ10-related enzymes NADH-oxidase and succinoxidase.
Chlorpromazine (e.g. Largactil)	Vitamin E	Reduced drug effects.	Observe.	According to in vitro research, vitamin E inhibits drug uptake in human cultured fibroblasts — clinical significance unknown.
Atypical anti-psychotic agents				
Olanzapine (e.g. Clozapine)	Ginkgo	Enhanced drug effects.	Beneficial interaction possible under professional supervision.	According to placebo-controlled trial, ginkgo may enhance drug effect on negative affect refractory schizophrenic patients.
CNS agents				
Cholinergic drugs (tacrine [e.g. Cognex])	Brahmi	Additive effects.	Observe — beneficial interaction possible under professional supervision.	Cholinergic activity has been identified for brahmi, so increased drug activity is theoretically possible.
	Ginkgo biloba	Additive effects.	Observe — beneficial interaction possible.	Cholinergic activity has been identified for ginkgo, so increased drug activity is theoretically possible.
	Lemon balm	Additive effects.	Observe — beneficial interaction possible.	Cholinergic activity has been identified for lemon balm, so increased drug activity is theoretically possible.
	St Mary's thistle	Reduced side effects.	Beneficial interaction possible.	St Mary's thistle may exert hepatoprotective activity against liver damage induced by tacrine.
CNS stimulants	Green tea	Additive effect.	Observe.	Theoretical increase of CNS-stimulant effects of drugs such as nicotine and beta-adrenergic agonists — clinical significance is unknown.
	Guarana	Additive effects.	Exercise caution.	Herb has demonstrated CNS-stimulant activity.
	Tyrosine	Additive effects.	Exercise caution.	Tyrosine is a precursor for several neurotransmitters.
Amphetamines	Tyrosine	Increased side effects.	Observe.	Tyrosine (200 and 400 mg/kg) has been shown to increase side effects of anorexia caused by ephedrine and amphetamine in a dose-dependent manner in rats — clinical significance unknown.
Methylphenidate	Zinc	Improved drug efficacy.	Beneficial interaction possible.	Clinical study of ADHD children with co-administration of 15 mg zinc for 6 weeks demonstrated improved drug efficacy.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Movement disorders				
L-Dopa (levodopa)	Calcium	Reduced drug absorption.	Separate doses by 2 hours.	L-dopa can form an insoluble complex with calcium.
	Iron	Reduced drug effect.	Separate doses by 2 hours.	May reduce bioavailability of carbidopa and L-dopa, which can form an insoluble complex with iron.
	Kava kava	Reduced drug effects.	Avoid unless under medical supervision.	Theoretical interaction, as dopamine antagonist effects have been reported for kava kava.
	Magnesium	Reduced drug absorption.	Separate doses by 2 hours.	L-dopa can form an insoluble complex with magnesium.
	SAMe	Reduced drug effectiveness.	Observe.	Theoretical interaction, as SAMe methylates levodopa. Interaction not observed clinically.
	Tyrosine	Decreased drug and tyrosine effect.	Avoid unless under medical supervision.	L-Dopa competes with tyrosine for uptake, so concurrent use may decrease uptake of both substances, thereby reducing efficacy.
	Vitamin B_6 (pyridoxine)	Increased nutrient requirements.	Observe — beneficial interaction possible under medical supervision.	L-dopa can cause hyperhomocysteinaemia in Parkinson's disease (PD) patients, relative to vitamin B status. Vitamin B requirements are higher in L-dopa treated patients, as such supplementation may be warranted in PD patients.
	Vitamin C	Reduced side effects.	Beneficial interaction possible.	A case report of co-administration with vitamin C suggests this may reduce drug side effects.
	Zinc	Reduced drug absorption.	Separate doses by 2 hours.	L-Dopa can form an insoluble complex with zinc.
L-Dopa with carbidopa	Iron	Reduced drug effect.	Separate doses by at least 2 hours.	May reduce bioavailability of carbidopa and L-dopa, which can form an insoluble complex with iron.
Sedatives, hypnotics				
CNS sedatives	Eucalyptus	Additive effects.	Exercise caution.	Theoretical interaction, as oral ingestion of eucalyptus has been associated with CNS depression.
	Green tea	Additive effects.	Observe.	Theoretically, high intakes can decrease the CNS-depressant effects of drugs such as benzodiazepines — clinical significance is unknown.
	Guarana	Reduced drug effects.	Observe.	Theoretically, guarana may reduce the sedative effects of drug via its CNS-stimulant effects; however, an in vivo study found no interaction with pentobarbital.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Hops	Additive effects.	Observe.	Additive effects theoretically possible, generating increased sedation; interaction may be beneficial in benzodiazepine withdrawal.
	Kava kava	Additive effects.	Exercise caution. Monitor drug dosage — beneficial interaction possible under medical supervision.	May be useful in benzodiazepine withdrawal.
	Lavender	Additive effects.	Observe — beneficial interaction possible under professional supervision.	Theoretically, lavender may potentiate the effects of sedatives.
	Passionflower	Additive effects.	Exercise caution. Beneficial interaction possible under medical supervision — monitor drug dosage.	Increased sedation; interaction may be beneficial in benzodiazepine withdrawal.
	Valerian	Additive effects.	Observe — beneficial interaction possible under medical supervision.	Increased sedation; interaction may be beneficial in benzodiazepine withdrawal.
Midazolam (e.g. Hypnovel)	St John's wort	Reduced drug effects.	Exercise caution. Monitor for signs of reduced drug effectiveness and adjust the dose if necessary.	St John's wort may increase drug metabolism and so reduce serum levels of drug.
Barbiturates	Albizia	Additive effects.	Exercise caution — beneficial interaction possible under medical supervision.	Potentiating of phenobarbitone-induced sleeping was observed in vivo — clinical significance unknown.
	Andrographis	Additive effects.	Observe — beneficial interaction possible under medical supervision.	Potentiating effects observed in vivo — clinical significance unknown.
	Folate	Reduced drug effects.	Exercise caution. Monitor for signs of reduced drug effectiveness.	Concomitant folic acid use can reduce seizure control — supervision may be required.
	Kava kava	Additive effects.	Exercise caution. Beneficial interaction possible under medical supervision — monitor drug dosage.	Increased sedation effects.
	Lemon balm	Additive effects.	Observe — beneficial interaction possible under medical supervision.	Increased sedation effects; one animal study found increased sedative effects from co-administration of lemon balm and pentobarbital — clinical significance unknown.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Passionflower	Additive effects.	Exercise caution. Beneficial interaction possible under medical supervision — monitor drug dosage.	Additive CNS sedation is theoretically possible.
	St John's wort (may not relate to low-hyperforin-containing products)	Reduced drug effects.	Avoid — monitor drug requirements. When St John's wort is started or ceased, monitor serum levels and alter drug dosage as required.	St John's wort induces CYP enzymes and P-glycoprotein, so can reduce drug serum levels.
	Slippery elm	Decreased drug absorption.	Separate doses by at least 2 hours.	Theoretical interaction — clinical significance unknown.
	Valerian	Additive effects.	Observe — beneficial interaction possible under medical supervision.	Increased sedation; interaction may be beneficial in benzodiazepine withdrawal.
	Vitamin B_6 (pyridoxine)	Reduced plasma levels and drug effects.	Caution. Monitor for drug effectiveness.	Concomitant B_6 use can reduce seizure control — supervision may be required.
	Withania	Additive effects.	Observe — beneficial interaction possible under medical supervision	Theoretically may increase sedation.
Benzodiazepines	Chamomile	Additive effects.	Observe — beneficial interaction possible under medical supervision.	Theoretically, an additive effect can occur with concurrent use.
	Kava kava	Additive effects.	Exercise caution. Beneficial interaction possible under medical supervision — monitor drug dosage.	Combination has been used to ease symptoms of benzodiazepine withdrawal under medical supervision.
	Passionflower	Additive effects at high doses.	Exercise caution. Beneficial interaction possible under medical supervision — monitor drug dosage.	May be useful in benzodiazepine withdrawal.
	St John's wort	Decreased drug effects.	Exercise caution — monitor for signs of reduced drug effectiveness.	St John's wort induces CYP enzymes and P-glycoprotein, so can reduce drug serum levels.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Valerian	Additive effects.	Observe — beneficial interaction possible under medical supervision.	Combination has been used to ease symptoms of benzodiazepine withdrawal under medical supervision.
	Withania	Additive effects.	Observe — beneficial interaction possible under medical supervision.	Increased sedative effect theoretically possible.
CONTRACEPTIVE AGENTS				
Combined oral contraceptive agents				
Oral contraceptive pill (OCP)	Chaste tree	Reduced herb effects.	Observe.	There has been speculation as to whether chaste tree is effective when OCP is being taken. Several clinical studies conducted in women taking OCP have confirmed that chaste tree still reduces symptoms of premenstrual syndrome.
	Folate	Reduced folate levels.	Beneficial interaction possible.	Folate levels are reduced with long-term use. Increased intake may be required with long-term therapy.
	Licorice	Increased side effects.	Observe. Exercise caution with high-dose licorice (> 100 mg/day glycyrrhizin) or long-term use (> 2 weeks). Monitor patients closely.	Increased risk of side effects such as hypokalaemia, fluid retention and elevated blood pressure have been noted in case reports.
	St John's wort	Reduced drug effects.	Exercise caution — avoid use with low-dose OCP.	Breakthrough bleeding has been reported in 12 cases, which may indicate decreased effectiveness. Caution related to hyperforin content. Recent investigations demonstrate low hyperforin extracts appear safe with OCP use.
	Vitamin A	Increased vitamin A levels.	Exercise caution with large doses of retinol.	OCP increases serum vitamin A levels due to longer storage in the liver.
	Vitamin B_2 (riboflavin)	Reduced vitamin B_2 levels.	Beneficial interaction possible.	OCP may increase demand for vitamin B_2. Increased intake may be required with long-term therapy.
	Vitamin B_3 (niacin)	Reduced vitamin B_3 levels.	Beneficial interaction possible.	Increased intake may be required with long-term therapy.
	Vitamin B_5 (pantothenic acid)	Reduced vitamin B_5 levels.	Beneficial interaction possible.	Increase dietary intake of foods rich in vitamin B_5 or consider supplementation.
	Vitamin B_6 (pyridoxine)	Reduced vitamin B_6 levels.	Beneficial interaction possible.	OCP may induce pyridoxine deficiency. Increase dietary intake of foods rich in vitamin B_6 or consider supplementation.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Vitamin B_{12} (cobalamin)	Reduced vitamin B_{12} levels.	Observe for signs and symptoms of B_{12} deficiency — beneficial interaction possible.	OCP users showed significantly lower concentrations of cobalamin than controls in a clinical study; however, this may be due to an effect upon B_{12}-binding proteins. Increased intake may be required with long-term therapy.
ENDOCRINE AND METABOLIC DISORDERS				
Adrenal steroid hormones				
Corticosteroids	Calcium	Reduced side effects. Reduced nutrient status.	Beneficial interaction possible.	Through inhibiting vitamin D-mediated calcium absorption, overall levels may be decreased. Increased calcium intake may be required with long-term therapy.
	Chromium	Reduced side effects.	Beneficial interaction possible.	Corticosteroids increase urinary losses of chromium, and chromium supplementation has been shown to aid in recovery from steroid-induced diabetes mellitus.
	Licorice	Additive effects.	Beneficial interaction possible but patients should be monitored closely for corticosteroid excess.	Concurrent use of licorice preparations potentiates the effects of topical and oral corticosteroids (e.g. prednisolone) as glycyrrhizin inhibits the metabolism of prednisolone. Some practitioners use licorice to minimise requirements for, or to aid in withdrawal of, corticosteroid medications.
	Vitamin B_{12} (cobalamin)	Reduced nutrient status.	Monitor nutrient status — beneficial interaction possible.	Decreased B_{12} levels have been identified in serum and cerebrospinal fluid of multiple sclerosis patients following high-dose 1000 mg/10 days IV methylprednisolone. Supplementation may be indicated.
	Vitamin C	Reduced vitamin C effects.	Beneficial interaction possible.	May increase requirement for vitamin C based on in vitro and in vivo data. Increased intake may be required with long-term therapy.
	Vitamin D	Reduced nutrient status.	Beneficial interaction possible.	Decreases levels of active vitamin D via an unknown mechanism. During long-term therapy of oral or inhaled corticosteroids, vitamin D supplementation should be considered.
Betamethasone	L-Carnitine	Additive effects.	Beneficial interaction possible.	RCT has shown that a combination of low-dose betamethasone (2 mg/day) and L-carnitine (4 g/5 days) was more effective in preventing respiratory distress syndrome (7.3% vs 14.5%) and death (1.8% vs 7.3%) in preterm infants than high-dose betamethasone given alone (8 mg/2 days).
Agents affecting calcium and bone metabolism				
Alendronate (e.g. Fosamax) and etidronate (e.g. Didronel)	Calcium	Reduced drug absorption.	Separate doses by at least 2 hours.	Calcium may reduce drug absorption; however, adequate calcium is required for optimal drug effects.
	Iron	Reduced drug absorption.	Separate doses by at least 2 hours.	

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Magnesium	Reduced drug absorption.	Separate doses by at least 2 hours.	Magnesium may reduce drug absorption; however, adequate magnesium is required for optimal drug effects.
	Zinc	Reduced drug absorption.	Separate doses by at least 2 hours.	
Gonadal hormones				
Oestrogen	Chromium	Improved nutrient status.	Beneficial effects.	Women receiving HRT appear to have improved chromium status. Combination therapy has been suggested to inhibit IL-6.
	Hops	Additive effects.	Observe.	Theoretical interaction, based on mild oestrogenic effect of hops.
	Red clover	Reduced drug effects.	Observe.	Theoretically, if taken in large quantities phyto-oestrogens may compete with synthetic oestrogens for receptor binding; however, a review considered 2 mg/kg of red-clover-derived isoflavones to be a safe dose for most patients.
Oestrogen and progesterone	Calcium	Additive effects.	Beneficial interaction possible.	Possible beneficial interaction on bone mineralisation.
	Licorice	Increased side effects.	Observe. Exercise caution with high-dose licorice or long-term use (> 2 weeks).	OCP can increase sensitivity to glycyrrhizin side effects such as hypertension, fluid retention, hypokalaemia.
Testosterone	Licorice	Altered testosterone effect.	Observe. Monitor testosterone levels.	Contradictory evidence suggests possible effects on testosterone levels.
	Saw palmetto	Reduced drug effectiveness.	Observe. Monitor drug efficacy.	Theoretically may reduce effectiveness of therapeutic androgens.
Haemopoietic agents				
Erythropoietin	Ginseng — Korean	Enhanced drug effects.	Beneficial interaction possible.	The total saponin fraction has been shown to promote haemopoiesis — clinical significance for total herb unknown.
	Iron	Additive pharmacological effect.	Beneficial interaction possible.	IV iron supplementation demonstrated improved success of darbepoetin in chemotherapy-related anaemia without iron deficiency without increasing toxicity.
	Withania	Enhanced drug effects.	Beneficial interaction possible.	Animal studies indicate herb increases haematopoiesis — clinical significance unknown.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Antidiabetic agents				
Thioglitazones (e.g. rosiglitazone and pioglitazone)	Quercetin	Enhanced drug effects.	Exercise caution.	Due to potential for toxicity careful monitoring of hepatic and cardiac function is required.
Sulphonylurea antidiabetic (e.g. gliclazide)	St John's wort	Reduced drug effects.	Avoid — unless under professional supervision — monitor drug effectiveness.	St John's wort found to induce significant clearance of gliclazide.
Hypoglycaemic agents				
Hypoglycaemic (e.g. metformin) agents. Adverse effects associated with increased hypoglycaemic effects include sweating, hunger, depression, tremor and headaches.	Aloe vera	Additive effects.	Observe.	Oral aloe vera may have hypoglycaemic activity, so additive effects are theoretically possible.
	Andrographis	Additive effects.	Exercise caution — blood glucose levels should be checked regularly — beneficial interaction possible under professional supervision.	Andrographis has hypoglycaemic activity comparable to that of metformin in vivo, so additive effects are theoretically possible.
	Bilberry	Additive effects.	Observe.	Animal study identified that the constituent myrtillin exerts hypoglycaemic actions — relevance for bilberry unclear.
	Bitter melon	Additive effects.	Exercise caution. Monitor drug requirements — possible beneficial effect under professional supervision.	
	Chromium	Additive effects.	Exercise caution. Monitor drug requirements — beneficial interaction possible under professional supervision.	Clinical studies have shown that chromium has hypoglycaemic activity in some individuals.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Cinnamon	Additive effects.	Observe — potentially beneficial interaction under professional supervision.	Clinical studies have produced contradictory results.
	Damiana	Additive effects.	Observe.	Theoretically possible — clinical significance is unknown.
	Elder	Additive effects.	Observe.	Hypoglycaemic effects demonstrated in vitro — clinical significance is unknown.
	Eucalyptus	Additive effects.	Exercise caution — monitor blood glucose levels.	If used orally in combination with glucose-lowering agents may contribute to hypoglycaemia.
	Fenugreek	Additive effects.	Exercise caution — blood glucose levels should be checked regularly. Beneficial interaction possible under professional supervision.	
	Ginseng — Siberian	Additive effects.	Observe.	Speculation is based on IV use in animal studies and has not been observed in humans with oral dose forms.
	Green tea	Additive effects.	Observe.	High intake of caffeine-containing drinks can increase blood sugar; however, green tea is reported to be hypoglycaemic, which may negate this effect — clinical significance of combination uncertain.
	Gymnema sylvestre	Additive effects.	Exercise caution. Interaction may be beneficial — reduction in drug dose may be achieved.	Gymnema may theoretically enhance blood-glucose-lowering effects of insulin and hypoglycaemic agents.
	Horse chestnut	Additive effects.	Observe — monitor blood glucose levels.	Horse chestnut exerts hypoglycaemic activity. Concurrent use with hypoglycaemic agents requires monitoring of blood glucose levels — clinical significance is unclear.
	Myrrh	Additive effects.	Exercise caution — blood glucose levels should be checked regularly. Beneficial interaction possible.	Myrrh has been shown to increase glucose tolerance in both normal and diabetic rats — clinical significance unknown.
	Oats	Additive effects.	Exercise caution — beneficial interaction possible under medical supervision. Insulin requirements should be monitored.	In an uncontrolled pilot study, an oatmeal intervention reduced insulin requirements by 42.5%.
	Olive leaf extract	Additive effects.	Beneficial interaction possible under professional supervision — drug dose may need modification.	Olive leaf has demonstrated hypoglycaemic activity in animal models. Theoretically an interaction is possible, though speculative.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Psyllium	Additive effects.	Beneficial interaction possible under professional supervision. Drug dose may need modification.	Psyllium has clinically demonstrated a capacity to slow the absorption of glucose and modulate glucose response.
	Vitamin B_3 (niacin)	Increased drug requirement.	Exercise caution. Monitor drug effectiveness	Niacin may affect glycaemic control and increase fasting blood glucose levels, so medication doses may need to be reviewed.
Metformin	Vitamin B_{12} (cobalamin)	Decreased vitamin B_{12} levels.	Observe — monitor for signs and symptoms of deficiency.	In patients with type 2 diabetes, metformin has been shown to reduce B_{12} levels and increase homocysteine. Supplementation may be beneficial.
Sulfonylureas (e.g. glibenclamide)	Coenzyme Q10	Reduced drug side effects.	Beneficial interaction.	Co-administration reduces side effects of this drug class on CoQ10-related enzymes NADH-oxidase.
Thyroid hormones and antithyroid agents				
Levothyroxine (e.g. Oroxine)	Aloe vera	Decreased drug levels.	Observe.	Reduced serum levels of T3 & T4 have been reported in one IV study. Single case report of depressed thyroid hormones in patient ingesting 10 mL of aloe juice daily for 11 months. Hormone levels returned to normal after discontinuing aloe.
	Calcium	Reduced drug absorption.	Separate doses by 2–4 hours.	Calcium and thyroxine form an insoluble complex.
	Celery	Decreased drug effect.	Observe	One case report suggests that celery extract may reduce drug effects. Clinical significance unknown.
	Horseradish	Increased drug requirement.	Observe. Monitor thyroid function. Dose may need to be adjusted.	Isothiocyanates may inhibit thyroxine formation and be goitrogenic, although this has not been demonstrated clinically.
	Iron	Reduced drug effect	Observe — monitor thyroid function and L-thyroxine dose may need alteration. Separate doses by 2–4 hours.	Iron supplements may decrease absorption of thyroid medication; however, iron deficiency may impair the body's ability to make thyroid hormones.
	Magnesium	Reduced drug absorption.	Separate doses by 2–4 hours.	Magnesium and thyroxine form an insoluble complex together.
	Psyllium	Reduced drug absorption.	Separate dose by 1–½ hour. Dose may need to be adjusted under medical supervision.	Soluble fibre may decrease drug bioavailability.
	SAMe		Exercise caution. Drug monitoring may be warranted.	

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Tyrosine	Additive effects.	Observe.	Additive effects theoretically possible, as tyrosine is a precursor to thyroid hormones.
	Withania	Additive effects.	Observe.	An in vivo study reported that daily administration of *Withania somnifera* root extract enhanced serum T4 concentration. One case report of withania-induced thyrotoxicosis exists — further investigation required to confirm.
	Zinc	Reduced drug absorption.	Separate doses by 2–4 hours.	Zinc and thyroxine form an insoluble complex together.
EYE				
Glaucoma preparations				
Timolol eye drops	Coenzyme Q10	Reduced side effects.	Beneficial interaction possible.	A clinical trial of people with glaucoma found that oral CoQ10 reduced cardiovascular side effects of timolol eye drops without affecting intraocular pressure.
GASTROINTESTINAL SYSTEM				
Digestive supplements				
Pancreatin	Folate	Reduced folate absorption.	Separate doses by 2–3 hours.	Monitor for folate efficacy and folate status.
Anti-emetic drugs				
Metoclopramide	Shatavari	Additive effect possible.	Exercise caution.	In animal studies shatavari root exerts similar effects on gastric emptying to those of metoclopramide; therefore, additive effects are possible.
Hyperacidity, reflux and ulcers				
Aluminium-based antacids	Vitamin C	Increased aluminium absorption.	Separate doses by at least 2 hours.	Vitamin C increases the amount of aluminium absorbed.
Antacids	Folate	Reduced folate absorption.	Separate doses by 2–3 hours.	
	Iron	Reduced iron absorption.	Separate doses by at least 2 hours.	Reduced iron effect.
Anti-ulcer drugs				
Sucralfate (e.g. Carafate, Ulcyte)	Vitamin E	Reduced vitamin absorption.	Separate doses by at least 4 hours. Monitor vitamin status.	Increased vitamin intake may be required with long-term therapy.
	Calcium	Reduced calcium absorption.	Monitor calcium status.	Calcium supplementation may be required.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Gastric-acid inhibitors (proton-pump inhibitors [e.g. omeprazole], H_2-receptor antagonists [e.g. ranitidine])	Cranberry	Adjunct to treatment.	Beneficial interaction possible.	Concurrent use increased vitamin B_{12} absorption.
	Folate	Reduced folate absorption.	Separate doses by 2–3 hours.	
	Iron	Reduced effect of iron.	Monitor for iron efficacy and iron status.	Drug reduces gastric acidity and therefore iron absorption.
	Licorice	Adjunct treatment.	Beneficial interaction.	May enhance ulcer healing.
	St John's wort	Reduced drug effectiveness.	Monitor for signs of reduced drug effectiveness — adjust dose if necessary.	St John's wort decreases levels via CYP induction.
	Vitamin B_{12} (cobalamin)	Reduced B_{12} absorption.	Beneficial interaction possible. Monitor B_{12} status.	Studies show that omeprazole acutely decreases cyanocobalamin absorption in a dose-dependent manner. Supplementation may be required with long-term therapy.
Helicobacter pylori triple-therapy	Garlic	Additive effects.	Observe — interaction may be beneficial.	Garlic inhibits growth of *H. pylori* in vitro and in vivo, and two studies have shown a synergistic effect with omeprazole.
Laxatives				
	Aloe vera	Additive effects.	Exercise caution.	Anthraquinones have significant laxative activity and may increase adverse effects of griping.
GENITOURINARY SYSTEM				
Bladder function disorders				
5-alpha-reductase inhibitors (e.g. finasteride [e.g. Proscar])	Pygeum	Additive effects.	Beneficial interaction possible — drug requirements may need to be modified.	Exerts only a weak inhibition of 5-alpha-reductase.
	Saw palmetto	Additive effects.	Beneficial interaction possible — drug requirements may need to be modified.	Additive effect theoretically possible. Meta-analyses show that herb is beneficial for BPH and in vitro tests show it may also inhibit 5-alpha-reductase activity — clinical significance is unknown.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Stinging nettle root	Additive effects.	Beneficial interaction possible — drug requirements may need to be modified.	Clinical studies show nettle root improves symptoms of BPH.
IMMUNOLOGY				
Immune modifiers				
Cyclosporin	Baical skullcap	Reduced drug effects.	Avoid.	*S. baicalensis* decreased plasma levels in animal model — clinical significance unknown.
	Peppermint oil	Additive effects.	Avoid concurrent use unless under medical supervision.	Peppermint oil has been shown to increase the oral bioavailability of cyclosporin in animal studies — clinical significance unknown.
	Echinacea	Decreased drug effects.	Exercise caution.	Theoretically, the immunostimulant activity of the herb may reduce drug effects — clinical significance unknown.
	Goldenseal	Increased drug effects.	Exercise caution.	RCT found berberine 0.2 g tds × 3 m increased blood concentrations of cyclosporin A in renal transplant patients by 29.3% to that of cyclosporin A. Clinical significance of oral ingestion of goldenseal is unknown.
	Quercetin	Reduced drug effects.	Avoid.	Significant decrease in drug bioavailability demonstrated in animal studies.
	St John's wort	Reduced drug. effects.	Avoid.	Decreases plasma levels significantly within 3 days of concomitant use. Recent clinical study found effect is not significant when low hyperforin products are used.
	St Mary's thistle	Reduced drug side effects but possible increase of drug effects.	Exercise caution.	Decreases hepatotoxicity; however, herb may reduce drug metabolism, leading to increased effects — clinical significance unknown.
Interferon	Baical skullcap	Increased side effects.	Exercise caution.	There have been reports of acute pneumonitis due to a possible interaction between Sho-saiko-to preparation (containing baical skullcap) and interferon, which appears to be due to an allergic–immunological mechanism rather than direct toxicity.
Interferon-alpha	L-Carnitine	Reduced side effects.	Beneficial interaction possible under professional supervision.	Clinical trials with patients being treated with interferon-alpha for hepatitis C found a reduction in fatigue associated with treatment when L-carnitine 2 g/day was co-administered.
Tacrolimus (e.g. Prograf)	St John's wort	Reduced drug effects.	Avoid unless under medical supervision — monitor for signs of decreased drug effectiveness.	Decreased drug serum levels via CYP induction.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Vaccines				
Cholera	Zinc	Immunoadjuvant effect.	Beneficial interaction possible.	In a clinical study co-administration with zinc acetate improved seroconversion of vibriocidal antibodies in children in both faecal and serum titres.
Diphtheria, tetanus, pertussis (DTP) vaccine	Shatavari	Immunoadjuvant effect.	Beneficial interaction possible.	Animal model demonstrated improved antibody titres and immunoprotection on challenge.
Influenza virus vaccine	Ginseng — Siberian	Reduced side effects.	Beneficial interaction possible.	May reduce the risk of post-vaccine reactions.
INFECTIONS AND INFESTATIONS				
Antibiotics	Probiotics	Reduced side effects.	Beneficial interaction possible.	Reduces gastrointestinal and genitourinary side effects. A meta-analysis of nine studies found that *Lactobacilli* and *Saccharomyces boulardii* successfully prevent antibiotic-induced diarrhoea. Increase intake with antibiotic therapy.
	Soy	Reduced phyto-oestrogen effect.	Inhibits metabolism of isoflavones to equol through inhibition of intestinal microflora.	
	Vitamin B_1 (thiamin)	Reduced endogenous vitamin production.	Beneficial interaction possible.	Increase dietary intake or consider supplementation with long-term therapy.
	Vitamin B_2 (riboflavin)	Reduced endogenous vitamin production.	Beneficial interaction possible.	Increase dietary intake or consider supplementation with long-term therapy.
	Vitamin B_5 (pantothenic acid)	Reduced endogenous vitamin production.	Beneficial interaction possible.	Increase dietary intake or consider supplementation with long-term therapy.
	Vitamin B_6 (pyridoxine)	Reduced endogenous vitamin production.	Beneficial interaction possible.	Increase dietary intake or consider supplementation with long-term therapy.
Aminoglycosides (e.g. gentamicin)	Magnesium	Decreased magnesium absorption.	Exercise caution. Monitor for signs and symptoms of magnesium deficiency.	Aminoglycosides may deplete magnesium levels and result in neuromuscular weakness. Increased magnesium may be required with long-term therapy.
Glycopeptide antibiotics (e.g. vancomycin)	Ginseng — Korean		Beneficial additive effect possible.	In animal studies, co-administration of Korean ginseng and vancomycin treated for *Staphylococcus aureus* demonstrated 100% survival compared to 67% of animals treated with Korean ginseng or 50% of animals treated with vancomycin. Clinical human studies required.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Quinolone antibiotics (e.g. norfloxacin [e.g. Noroxin])	Calcium	Reduced drug absorption.	Separate antibiotic dose by at least 2 hours before or 4 hours after oral calcium.	
	Dandelion	Reduced drug absorption.	Separate doses by at least 2 hours.	Reduced drug absorption observed in an experimental study.
	Iron	Reduced drug absorption.	Take drug 2 hours before or 4–6 hours after iron dosing — monitor patient for antibiotic efficacy.	
	Magnesium	Reduced drug absorption.	Separate antibiotic dose by taking at least 2 hours before or 4 hours after oral magnesium.	
	Quercetin	Reduced drug effect.	Exercise caution.	Theoretical concern based on in vitro studies as quercetin may compete for bacterial binding site with antibiotics.
	Zinc	Reduced drug and zinc absorption.	Separate doses by at least 2 hours.	Complex formation between zinc and quinolones results in reduced absorption of both substances, with potential reduction in efficacy.
Tetracycline antibiotics (e.g. minocycline [e.g. Minomycin], doxycycline)	Calcium	Reduced drug and calcium absorption.	Separate doses by at least 2 hours.	Tetracyclines form insoluble complexes with calcium, thereby reducing its absorption.
	Iron	Reduced drug effect.	Separate doses by at least 4 hours.	Initial studies indicated tetracyclines form insoluble complexes with iron, thereby reducing its absorption. More recent investigations have found no effect on erythrocyte iron uptake. Monitor iron efficacy during long-term tetracycline use.
	Magnesium	Reduced drug and magnesium absorption.	Separate doses by at least 2 hours.	Tetracyclines form insoluble complexes with iron, thereby reducing its absorption.
	Vitamin A	Increased side effects.	Avoid.	Concomitant use may increase side effects such as headaches. Long-term use increases the risk of pseudotumour cerebri.
	Vitamin B_{12} (cobalamin)	Reduced drug absorption.	Separate doses by at least 2 hours.	B complexes containing B_{12} may significantly reduce the bioavailability of tetracycline hydrochloride.
	Zinc	Reduced drug and zinc absorption.	Separate doses by at least 2 hours.	Complex formation between zinc and tetracycline results in reduced absorption of both substances, with potential reduction in efficacy.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Other antibiotics and anti-infectives (trimethoprim [e.g. Triprim])	Folate	Reduced folate levels; reduced drug toxicity.	Exercise caution — beneficial interaction possible under medical supervision.	Monitor folate status; increased folate intake may be required with long-term or high-dose therapy.
Anthelmintic drugs				
Albendazole	Ginseng — Korean	Reduced drug effects.		In animal studies, co-administration found to accelerate intestinal clearance of anthelmintic; clinical significance unknown.
Antileishmanial drug				
Stibanate	Quercetin	Improved drug effect.	Beneficial interaction possible.	Concurrent use with quercetin appears to improve drug efficacy and reduce condition side effects of anaemia and parasitaemia.
Antimalarials				
Chloroquine (e.g. Chlorquin)	Vitamin E	Reduced drug effects.	Observe.	According to in vitro research, vitamin E inhibits drug uptake in human cultured fibroblasts — clinical significance unknown.
Pyrimethamine (e.g. Daraprim)	Folate	Reduced folate effects.	Beneficial interaction possible with folinic acid.	Impaired folate utilisation occurs with drug use — supplementation may be required.
Antituberculotics and antileprotics				
Cycloserine and isoniazid	Vitamin B_6 (pyridoxine)	Reduced B_6 levels.	Beneficial interaction possible.	Drug may induce pyridoxine deficiency. Increased dietary intake of vitamin B_6 rich foods or supplementation may be required with long-term therapy.
Isoniazid	Vitamin B_3 (niacin)	Reduced B_3 levels.	Beneficial interaction possible.	Prolonged isoniazid therapy (the drug replaces niacinamide in NAD) may induce pellagra. Increased vitamin intake may be required with long-term therapy.
	Vitamin E	Reduced vitamin absorption.	Separate doses by at least 4 hours and monitor vitamin status.	Increased vitamin intake may be required with long-term therapy.
Rifampicin and isoniazid	Vitamin D	Reduced vitamin D levels.	Beneficial interaction possible.	Drugs reported to induce catabolism of vitamin D. May be a concern for subjects already at risk of compromised vitamin status. Increase vitamin D intake with long-term therapy.
Antiviral agents				
Antiretroviral drugs	Vitamin B_3 (niacin)	Reduced drug side effects.	Beneficial interaction under professional supervision.	Extended release niacin may improve the dyslipidaemia associated with antiretroviral therapy and is considered a safe and effective therapeutic option.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
HIV drugs (e.g. zidovudine [AZT, e.g. Retrovir])	L-Carnitine	Reduced carnitine levels.	Beneficial interaction possible.	In vitro studies indicate prevention of muscle damage due to carnitine depletion. Increased intake may be required with long-term therapy.
	Ginseng — Korean	Delayed viral resistance.	Beneficial interaction possible.	Long intake of Korean ginseng in HIV-1 infected patients demonstrated delay in resistance mutation to zidovudine.
HIV non-nucleoside transcriptase inhibitors	St John's wort	Reduced drug effects.	Avoid.	St John's wort increases drug metabolism, thereby reducing drug serum levels.
HIV protease inhibitors	St John's wort	Reduced drug effects.	Avoid.	St John's wort increases drug metabolism, thereby reducing drug serum levels.
Saquinavir	Garlic	Reduced drug effects.	Avoid until safety can be established.	Clinical studies have generated conflicting results: one clinical study found that garlic reduces serum levels of saquinavir and therefore drug efficacy, whereas a subsequent study found no significant effect on drug pharmacokinetics.
	Quercetin	Possible reduced drug effects.	Exercise caution.	Co-administration does not appear to alter saquinavir; however, owing to substantial subject variability of drug concentrations caution should be exerted until more is known.
MUSCULOSKELETAL SYSTEM				
Non-steroidal anti-inflammatory drugs				
	Celery seed extract	Reduced side effects.	Beneficial interaction possible.	Gastroprotective activity seen in animal model.
	Chamomile	Reduced side effects.	Interaction is beneficial.	Gastroprotective activity seen in animal model.
	Chondroitin	Additive effects.	Beneficial interaction possible. Drug dosage may require modification.	May enhance the anti-inflammatory effects of the NSAID.
	Colostrum	Reduced side effects.	Interaction is beneficial.	Has gastroprotective activity.
	Devil's claw	Additive effects.	Beneficial interaction possible. Drug dosage may require modification.	May enhance the anti-inflammatory effects of the NSAID.
	Fish oils	Additive effects.	Beneficial interaction possible. Drug dosage may require modification.	May enhance the anti-inflammatory effects of the NSAID.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Ginger	Additive effects.	Beneficial interaction possible. Drug dosage may require modification.	May enhance the anti-inflammatory effects of NSAIDs at high doses.
	Glucosamine	Additive effects.	Beneficial interaction possible. Drug dosage may require modification.	Theoretically may enhance the anti-inflammatory effects of the NSAID.
	Glutamine	Reduced side effects.	Beneficial interaction possible.	May ameliorate the increased intestinal permeability caused by indomethacin.
	New Zealand green-lipped mussel	Additive effects.	Beneficial interaction possible. Drug dosage may require modification.	Anti-inflammatory activity reported in a clinical study — may enhance the anti-inflammatory effects of the NSAID.
	Stinging nettle	Additive effects.	Beneficial interaction possible. Drug dosage may require modification.	Anti-inflammatory activity reported in a clinical study — may enhance the anti-inflammatory effects of the NSAID.
	SAMe	Additive effects.	Beneficial interaction possible. Drug dosage may require modification.	Anti-inflammatory activity reported in a clinical study — may enhance the anti-inflammatory effects of the NSAID.
	Vitamin E	Additive effects.	Beneficial interaction possible. Drug dosage may require modification.	May enhance the pain-modifying effects of the NSAID when used in high doses for RA.
	Willow bark	Additive effects.	Beneficial interaction possible. Drug dosage may require modification.	May enhance the anti-inflammatory effects of the NSAID.
	Zinc	Reduced absorption.	Separate doses by at least 2 hours.	
Diclofenac sodium (topical)	Licorice	Additive effects.	Beneficial interaction possible.	In vitro studies have shown that the addition of glycyrrhizin enhanced the topical absorption of diclofenac sodium — significance for licorice unknown.
Sulfasalazine (e.g. Salazo-pyrin)	Folate	Reduced drug absorption.	Separate doses by 2–3 hours.	
	Iron	Reduced drug and iron effects.	Separate doses by at least 2 hours.	May bind together and reduce absorption of both.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
NEOPLASTIC DISORDERS				
Chemotherapy	Ginseng — Korean	Reduced side effects. May improve drug response.	Beneficial interaction possible under medical supervision but further research required to confirm.	Preliminary evidence suggests Korean ginseng may reduce nausea and vomiting associated with chemotherapy and radiation by antagonising serotonin receptors. Ginseng may also sensitise cancer cells to chemotherapeutic agents.
	Ginseng — Siberian	Reduced drug effects — improved treatment tolerance.	Exercise caution — possible beneficial interaction under medical supervision but further research required to confirm.	Increased tolerance for chemotherapy and improved immune function demonstrated in women with breast and ovarian cancer. Theoretically, co-administration may reduce drug effects; however, improves immune function.
	L-Glutamine	Reduced side effects.	Beneficial interaction possible under medical supervision.	Number of clinical trials have demonstrated that glutamine supplementation improves side effects such as oral pain and inflammation, increased gut permeability and reduced lymphocyte count.
	Rosemary	Increased drug effects of P-gp substrates.	Exercise caution with concentrated extracts until clinical significance determined.	Inhibits P-glycoprotein, so may affect the bioavailability of P-gp substrates.
	Vitamin A	May improve drug response.	Beneficial interaction possible under medical supervision but further research required to confirm.	Adjunctive treatment may improve drug response; consider individual patient characteristics, form and presentation of cancer, and drugs before administration.
	Vitamin C	May enhance anti-tumour activity.	Beneficial interaction possible.	Controversial — further research required.
	Withania	Reduced side effects.	Observe. Beneficial interaction possible under medical supervision but further research required to confirm.	Animal studies suggest a potential role for withania as an adjunctive treatment during chemotherapy for the prevention of drug-induced bone marrow suppression — clinical significance unknown.
Myelosuppression	Echinacea	Reduced side effects.	Beneficial interaction possible under professional supervision.	Use of echinacea between chemotherapy treatment cycles theoretically may improve white cell counts and reduce dose limiting toxicities on myelopoeisis.
Anti-oestrogen (e.g. Tamoxifen)	Hops	Reduced drug effects.	Exercise caution until confirmed clinically.	Theoretically hops may alter the effectiveness of these drugs owing to the herb's oestrogenic activity.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Soy	May enhance drug effect.	Potential beneficial interaction under professional supervision.	Recent large prospective study found soy isoflavones consumed at comparative levels to those in Asian populations may reduce the risk of cancer recurrence in women receiving tamoxifen therapy and does not appear to interfere with tamoxifen efficacy. In vivo studies indicate soy isoflavone daidzein may enhance tamoxifen activity against breast cancer burden and incidence — usual dietary intake appears safe but the safety of concentrated extracts is yet to be established.
	Vitamin B_3 (niacin)	Improved drug activity and mitochondrial function.	Beneficial interaction possible under professional supervision.	The adjunct of B_2, B_3 and CoQ10 to tamoxifen therapy demonstrated both improved mitochondrial antioxidant status and antitumour activity. Exact mechanism of niacin is unclear; however, combination therapy may be advantageous.
	Vitamin C	Enhanced drug effects.	Beneficial interaction possible under professional supervision.	In vivo study indicated vitamin C enhanced tamoxifen antitumour activity — potentially beneficial but difficult to assess.
Proteasome inhibitor (e.g. Bortezomib, velcade)	Green tea	Reduced drug effects.	Avoid.	In vitro and in vivo green tea extract almost completely blocked the effects of bortezomib.
	Vitamin C	Reduced drug effects.	Avoid.	Vitamin C inactivated drug activity in vitro.
Topoisomerase enzyme inhibitor (e.g. Irinotecan)	St John's wort	Reduced drug effects.	Exercise caution. Monitor for signs of reduced drug effectiveness and adjust the dose if necessary.	St John's wort may increase drug metabolism and so reduce serum levels of drug.
Topoisomerase enzyme inhibitor (e.g. Etoposide)	Vitamin C	Enhanced drug effects.	Beneficial interaction possible under medical supervision.	Vitamin C enhanced the antitumour activity of etoposide in vitro — potentially beneficial but difficult to assess.
Alkylating agents				
Cyclophosphamide	Astragalus		Possibly beneficial under professional supervision.	
	Echinacea	Increased drug effects.	Avoid in autoimmune disease.	Echinacea appears to increase the immunostimulatory effect of low-dose cyclophosphamide — clinical significance unknown.
	Rhodiola	Enhanced drug effects and reduced drug-side effects.	Beneficial interaction under professional clinical supervision.	In animal models combination therapy has demonstrated enhanced antitumour and antimetastatic action. In addition reduced drug-toxicity in bone marrow was observed.
	Turmeric	Reduced drug effects.	Avoid until confirmed clinically.	Animal studies indicate reduced drug efficacy.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Withania	Reduced drug effects. Reduced side effects/ toxicity.	Exercise caution.	The ability to stimulate stem-cell proliferation has led to concerns that withania could reduce cyclophosphamide-induced toxicity and therefore reduce its usefulness in cancer therapy, although preliminary animal studies indicate a potential role as a potent and relatively safe radiosensitiser and chemotherapeutic agent. Theoretically it may also decrease the effectiveness of other immunosuppressant drugs.
	Vitamin C	Enhanced drug effects.	Beneficial interaction possible under professional supervision.	In vivo study demonstrated enhanced drug effects; potentially beneficial but difficult to assess.
	Herbs with immunostimulant properties (e.g. echinacea, andrographis, astragalus, baical skullcap, garlic, Korean ginseng, pelargonium, Siberian ginseng)	Reduced drug effects.	Observe.	Theoretically, immunostimulating agents may reduce drug effectiveness; however, clinical significance is unknown.
Antibiotic cytotoxics				
Doxorubicin (e.g. adriamycin)	Black cohosh	Increased drug cytoxicity.	Avoid until safety can be confirmed.	Black cohosh increased the cytotoxicity of doxorubicin in experimental model; clinical significance unknown.
	L-Carnitine	Reduced side effects.	Beneficial interaction possible. Use only under professional supervision.	Animal and human studies suggest that long-term carnitine administration may reduce the cardiotoxic side effects of adriamycin — further research required.
	Coenzyme Q10	Reduced side effects.	Beneficial interaction possible.	Animal and human studies suggest that the cardiotoxic side effects of adriamycin are reduced with CoQ10 supplementation — further research required.
	Ginkgo biloba	Reduced side effects.	Beneficial interaction possible.	Animal studies suggest ginkgo reduces hyperlipidaemia and proteinuria associated with adriamycin-induced nephropathy, which may enhance drug therapeutic index. Clinical trials have not been conducted to confirm this activity. In vivo research suggests that ginkgo can prevent doxorubicin-induced cardiotoxicity, although no human studies are available to confirm this activity.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Quercetin	Reduced side effects.	Beneficial interaction.	In an animal study, administration of quercetin has exerted a protective effect against the cardiotoxic effects of adriamycin; no human studies available. In human breast cancer cells, quercetin appears to inhibit the formation of cardiotoxic doxorubicinol.
	Rhodiola	Reduced drug side effects.	Beneficial interaction under clinical supervision.	Rhodiola is shown to reduce liver dysfunction without altering adriamycin's antitumour effects.
	St Mary's thistle	Increased drug effectiveness and reduced drug side effects.	Beneficial interaction — under professional supervision.	Silymarin reduces cardiotoxicity and possibly chemosensitises resistant cells to anthracyclines.
	Vitamin C	Reduces side effects and enhances therapeutic action.	Beneficial interaction possible.	Vitamin C enhanced the therapeutic drug effect and reduced drug toxicity in vivo. Potentially beneficial but difficult to assess.
	Vitamin E	Reduced side effects.	Beneficial interaction possible.	One study found that oral DL-alpha-tocopheryl acetate (1600 IU/day) prevented doxorubicin-induced alopecia; however, the same dosage failed to prevent alopecia after doxorubicin treatment post-mastectomy for breast cancer and also failed to prevent alopecia in second study.
	Withania	Reduced drug side effects.	Beneficial interaction possible.	In withania-pretreated animals, attenuation of doxorubicin-induced cardiocytoxic side effects occurred.
Bleomycin	Ginkgobiloba	Reduced side effects.	Beneficial interaction possible.	Animal studies suggest ginkgo reduces drug induced oxidative stress and improves drug tolerance. Clinical studies are necessary to confirm this.
Antimetabolites				
Docetaxel	Black cohosh	Increased drug effects.	Exercise caution.	Increased cytotoxicity of docetaxel observed in experimental model — clinical significance unclear.
Methotrexate	Folate	Reduced side effects but may reduce drug response.	Exercise caution in cancer treatment. Observe in other conditions — medical supervision advised.	Methotrexate is a folate antagonist drug; supplementation may reduce toxicity. This action may be problematic in cancer treatment and reduce drug response, but may be beneficial in other uses.
Paclitaxel	Licorice	Additive effects.	Observe. Beneficial interaction may be possible under medical supervision — further research required.	A constituent of licorice has been demonstrated to significantly potentiate the effects of paclitaxel in vitro — clinical significance for licorice unknown.
	Quercetin	Increased drug effects.	Exercise caution. Drug doses may need adjustment — further research required.	Increased drug bioavailability seen in animal study.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Withania	Potentiates chemotherapeutic effect.	Beneficial interaction possible under medical supervision — further research required.	Co-administration in animal studies has demonstrated enhanced chemotherapeutic effects through modulation of protein-bound carbohydrates and marker enzymes. Combination therapy has shown potential in treatment of benzo(a)pyrene-induced lung cancer through increased antioxidant capacity and attenuation of cell proliferation.
Immunosuppressant drugs				
	Andrographis	Reduced drug effects.	Exercise caution.	Immunostimulant activity has been demonstrated in vivo.
	Astragalus	Reduced drug effects.	Exercise caution.	Due to known immunostimulant effects observed clinically.
	Baical skullcap	Reduced drug effects.	Exercise caution.	Due to known immunostimulant effects observed clinically.
	Echinacea	Reduced drug effects.	Exercise caution.	Due to known immunostimulant effects observed clinically.
	Garlic	Reduced drug effects.	Exercise caution.	Due to known immunostimulant effects observed clinically.
	Ginseng — Korean and Ginseng — Siberian	Reduced drug effects.	Exercise caution.	Due to known immunostimulant effects observed clinically.
Cisplatin	Black cohosh	Reduced side effects.	Beneficial interaction may be possible under professional supervision — further research required.	In an experimental breast cancer model, black cohosh decreased the cytotoxicity of cisplatin — clinical significance unknown.
	L-Carnitine	Reduced side effects.	Beneficial interaction possible under professional supervision.	Treatment with carboplatin results in marked urinary losses of L-carnitine. Research into the use of L-carnitine 4 g/day for 7 days showed reduced fatigue from treatment with cisplatin.
	Ginger	Reduced side effects.	Beneficial interaction possible under professional supervision — further research required.	Pretreatment with ginger has restored testicular antioxidant parameters and sperm motility in cisplatin-induced damage — clinical significance unknown.
	Ginkgo biloba	Reduced side effects.	Beneficial interaction possible under professional supervision.	Ginkgo has been indicated in two in vivo studies to reduce nephrotoxic effects of cisplatin. Animal models have indicated the use of ginkgo in protecting against cisplatin-induced cytotoxicity. Clinical trials are required to confirm clinical significance.
	Pelargonium	Reduced drug effectiveness.	Avoid.	Avoid until safety can be established.
	Quercetin	Increased drug effects.	Beneficial interaction theoretically possible under professional supervision.	Pretreatment may sensitise human cervix carcinoma cells to drug according to preliminary research — further research required.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	St John's wort	Reduced side effects.	Beneficial interaction. Monitor under professional supervision.	Clinical study found St John's wort inhibited cisplatin-induced kidney histological abnormalities. St John's wort did not alter serum drug concentrations.
	St Mary's thistle	Increased drug effects. Reduced side effects.	Beneficial interaction possible under professional supervision.	Preliminary research has shown that this combination may reduce toxicity effects yet enhance antitumour activity — further research required.
	Selenium	Reduced side effects.	Beneficial interaction possible under professional supervision.	In vitro and in vivo studies indicate that selenium may reduce drug-associated nephrotoxicity, myeloid suppression and weight loss — further research required.
	Vitamin C	Increased drug effects — reduced side effects.	Beneficial interaction possible under professional supervision.	In vitro and in vivo studies indicate that vitamin C enhanced the antitumour activity of cisplatin and reduce drug toxicity — potentially beneficial but difficult to assess.
	Vitamin E	Reduced side effects.	Beneficial interaction possible under professional supervision.	A review of 4 clinical trials with concomitant use of vitamin E and cisplatin demonstrated significant reduction in chemotherapy-induced peripheral neuropathy in all trials.
	Withania	Reduced drug effects.	Exercise caution — beneficial interaction may be possible under professional supervision.	The ability to stimulate stem cell proliferation has led to concerns *W. somnifera* could reduce the effectiveness of immunosuppressant drugs.
Interleukin-2-immunotherapy	L-Carnitine	Reduced side effects.	Beneficial interaction possible under professional supervision.	Clinical trials using L-carnitine (1000 mg/day orally) found that it may successfully prevent cardiac complications during IL-2-immunotherapy in cancer patients with clinically relevant cardiac disorders.
Vinca alkaloids				
Vinblastine	Licorice	Has additive effects.	Observe. Beneficial interaction possible under medical supervision.	A constituent of licorice has been demonstrated to significantly potentiate the effects of vinblastine in vitro — clinical significance unknown.
Vincristine	Vitamin C	Has additive effects.	Beneficial interaction possible under medical supervision.	Vitamin C enhanced drug's effect in vivo — potentially beneficial but difficult to assess.
Radiotherapy				
	Zinc	Reduced plasma nutrient status.	Beneficial interaction under professional supervision.	Radiotherapy reduces plasma zinc levels.
NUTRITION				
Anorectics and weight-reducing agents				
Orlistat (e.g. Xenical)	Lutein and zeaxanthin	Reduced vitamin absorption.	Long-term administration may reduce plasma levels.	Increased vitamin intake may be required with long-term therapy.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	Lycopene	Reduced vitamin absorption.	Separate doses by at least 2 hours. Monitor vitamin status.	Drugs that reduce fat absorption may reduce lycopene absorption. Increased vitamin intake may be required with long-term therapy.
	Vitamin A	Reduced vitamin absorption.	Separate doses by at least 4 hours. Monitor vitamin status.	Increased dietary intake of food rich in vitamin A or consider supplementation with long-term therapy.
	Vitamin D	Reduced vitamin absorption.	Separate doses by at least 4 hours either side of drug. Monitor vitamin status.	Concurrent supplementation of multivitamin with vitamin D is advised.
	Vitamin E	Reduced vitamin absorption.	Separate doses by at least 4 hours. Monitor vitamin status.	Increased vitamin intake may be required with long-term therapy.
	Vitamin K	Reduced vitamin absorption.	Separate doses by at least 4 hours. Monitor vitamin status.	Increased vitamin intake may be required with long-term therapy.
POISONING, TOXICITY AND DRUG DEPENDENCE				
Agents used in drug dependence				
Methadone	Kava kava	Has additive effects.	Exercise caution.	Increased sedation theoretically possible.
	St John's wort	Reduced drug effects.	Avoid.	Decreases serum levels via CYP induction.
Detoxifying agents, antidotes				
Penicillamine (e.g. D-penamine)	Calcium	Reduced drug effects.	Separate doses by 2 hours.	Combination forms insoluble complex.
	Iron	Reduced drug and iron effects.	Separate doses by at least 2 hours. Do not suddenly withdraw iron.	Sudden withdrawal of iron during penicillamine use has been associated with penicillamine toxicity and kidney damage.
	Magnesium	Reduced drug effects.	Separate doses by 2 hours	Combination forms insoluble complex.
	Vitamin B_6 (pyridoxine)	Reduced B_6 effect.	Beneficial interaction possible.	Drug may induce pyridoxine deficiency — increase intake of vitamin B_6 rich foods or consider supplementation.
	Zinc	Reduced drug effects.	Separate doses by 2 hours.	Combination forms insoluble complex.
RESPIRATORY SYSTEM				
Broncospasm relaxants				
Ephedrine	Tyrosine	Increased side effects.	Observe.	Tyrosine (200 and 400 mg/kg) has been shown to increase side effects of anorexia caused by ephedrine and amphetamine in a dose-dependent manner in rats — clinical significance unknown.

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
Theophylline	St John's wort	Reduced drug effects.	Monitor for signs of reduced drug effectiveness and adjust the dose if necessary.	Decreased drug serum levels.
	Vitamin B_6 (pyridoxine)	Reduced B_6 levels	Beneficial interaction possible.	Drug may induce pyridoxine deficiency. Increased intake may be required with long-term therapy.
Expectorants, antitussives, mucolytics and decongestants				
	Adhatoda	Increased drug effects.	Observe.	Results from animal studies show that *Adhatoda vasica* extract exerts considerable antitussive activity when administered orally and is comparable to codeine when cough is due to irritant stimuli.
Phenylpropanolamine (found in Neo-Diophen)	Tyrosine	Increased side effects.	Observe.	Tyrosine (200 and 400 mg/kg) has been shown to increase side effects of anorexia caused by phenylpropanolamine in a dose-dependent manner in rats — clinical significance unknown.
SKIN				
Acne, keratolytics and cleansers				
Isotretinoin (e.g. Roaccutane)	Vitamin A	Has additive effects.	Avoid.	Isotretinoin is a vitamin A derivative, so adverse effects and toxicity may be increased.
Psoriasis, seborrhoea and ichthyosis				
Ketoconazole (e.g. Nizoral)	Vitamin D	Reduced vitamin D effects.	Compromised vitamin status.	Ketoconazole reduces the conversion of vitamin D to its active forms. Increased intake may be required with long-term therapy.
Topical corticosteroids				
Topical corticosteroids (e.g. hydrocortisone)	Aloe vera (topical)	Has additive effects.	Beneficial interaction possible.	In addition to its own anti-inflammatory effects, animal studies have shown that aloe vera increases the absorption of hydrocortisone by hydrating the stratum corneum, inhibits hydrocortisone's antiwound-healing activity and increases wound tensile strength.
OTHER				
Alcohol	Andrographis	Reduced side effects.	Beneficial interaction possible.	May reduce hepatic injury.
	Ginseng — Korean	Reduced side effects.	Beneficial interaction possible.	May reduce hepatic injury.
	Kava kava	Has additive effects.	Observe.	Potentiation of CNS sedative effects have been reported in an animal study; however, one double-blind placebo-controlled study found no additive effects on CNS depression or safety-related performance.
	Magnesium	Reduced vitamin status.	Monitor for deficiency.	Chronic alcohol ingestion may lead to nutrient deficiency — consider increased intake.

Continued

Drug	Herb or supplement	Potential outcome	Recommendation	Evidence/Comments
	St Mary's thistle	Reduced side effects.	Beneficial interaction possible.	May reduce hepatic injury.
	SAMe	Reduced side effects.	Beneficial interaction possible.	May reduce hepatic injury caused by such agents as paracetamol, alcohol and oestrogens.
	Schisandra	Reduced side effects.	Beneficial interaction possible.	May reduce hepatic injury.
	Vitamin B_1	Reduced vitamin status.	Monitor for deficiency.	Chronic alcohol ingestion may lead to nutrient deficiency — consider increased intake.
	Vitamin B_2	Reduced vitamin status.	Monitor for deficiency.	Chronic alcohol ingestion may lead to nutrient deficiency — consider increased intake.
Colchicine	Vitamin A	Reduced vitamin A effects.	Monitor for deficiency — beneficial interaction possible.	Colchicine may interfere with vitamin A absorption and homeostasis.
Dopamine antagonists	Chaste tree	Reduced drug effects.	Observe.	Anatagonistic action theoretically possible.
Hepatotoxic drugs	Andrographis	Reduced side effects.	Beneficial interaction possible.	May exert hepatoprotective activity against liver damage induced by drugs such as paracetamol and tricyclic antidepressants.
	Garlic	Reduced side effects.	Beneficial interaction possible.	May exert hepatoprotective activity against liver damage induced by drugs such as paracetamol.
	Quercetin	Reduced side effects.	Interaction is beneficial.	Exerts hepatoprotective activity.
	St Mary's thistle	Reduced side effects.	Beneficial interaction possible.	May exert hepatoprotective activity against liver damage induced by drugs such as paracetamol.
	SAMe	Reduced side effects.	Beneficial interaction possible.	May exert hepatoprotective activity against liver damage induced by drugs such as paracetamol.
	Schisandra	Reduced side effects.	Beneficial interaction possible.	May exert hepatoprotective activity against liver damage induced by drugs such as paracetamol.
Lipophilic drugs	Chitosan	Reduced drug absorption.	Separate doses by at least 2 hours.	Binds to dietary fats and reduces their absorption and so can also affect the absorption of lipophilic drugs.
PUVA therapy	Celery	Has additive effects	Exercise caution.	While celery has been found to contain psoralens, celery extract does not seem to be photosensitising even after ingestion in large amounts; however, it may increase the risk of phototoxicity with concurrent PUVA therapy.
	St John's wort (hypericin component)	Has additive effects.	Exercise caution.	Hypericin may increase sensitivity to UV radiation.

APPENDIX 4

RESOURCES: TRAINING, MANUFACTURERS AND INFORMATION

COURSES IN AUSTRALIA

Listed below are universities, schools and colleges in Australia offering undergraduate or postgraduate courses in nutritional medicine, herbal medicine, naturopathy or complementary medicine.

Australian Capital Territory

Australian Institute of Applied Sciences, College of Natural Medicine
1/6 Napier Close, Deakin 2600

Canberra Institute of Technology
GPO Box 826, Canberra 2601

New South Wales

Australasian College of Natural Therapies
PO Box K1356, Haymarket 1240

Charles Sturt University, School of Biomedical Sciences
PO Box 588, Wagga Wagga 2678

College of Nepean Natural Therapeutics
Suite 12/20 Castlereagh St, Penrith 2750

Endeavour College of Natural Health
139 Alexander Street, Crows Nest, Sydney 2065

Gracegrove College
Level 1/723 Hunter St, Newcastle 2300
(PO Box 108, Newcastle 2300)

International Academy of Nutrition
Suite 4/21, Sydney Rd, Manly 2095
(PO Box 370, Manly 2095)

Nature Care College
46 Nicholson St, St Leonards 2065

NSW School of Natural Medicine
202 North Boambee Rd, Coffs Harbour 2450

Southern Cross Herbal School
PO Box 1195, Gosford 2250

Southern Cross University, School of Health & Human Sciences, Natural and Complementary Medicine
PO Box 157, Lismore 2480

Sydney College of Homeopathic Medicine (a campus of Endeavour College of Natural Health)
Level 2, 139 Alexander Street, Crows Nest 2065

University of Newcastle, School of Applied Sciences
University Drive, Callaghan 2308

University of Sydney, Faculty of Pharmacy
Sydney 2006

University of Technology Sydney, College of Traditional Chinese Medicine, Faculty of Science (incorporates the College of TCM)
15 Broadway, Ultimo 2007

University of Western Sydney
Narellan Road, Campbelltown 2560

Queensland

Aromatherapy College of Australia
Suite 3, 16–36 Nile St, Woolloongabba 4102

Australasian College of Natural Therapies
Unit 2, 10 Costin Street, Fortitude Valley 4006

Australian College of Phytotherapy
PO Box 661, Warwick 4370

Australian Institute of Applied Sciences, College of Natural Medicine
11 Beata Street, Stones Corner 4120

Endeavour College of Natural Health (formerly known as Australian College of Natural Medicine)
Brisbane Campus: 362 Water St, Fortitude Valley 4006
Gold Coast Campus: 105 Scarborough St, Southport 4215

Gold Coast Institute of TAFE Academy of Natural Therapies
91 Scarborough St, Southport 4215

Health Schools Australia
PO Box 94, Runaway Bay 4216

Naturopathic Correspondence College of Australia
1066 Dayboro Rd, Kurwongbah 4503

University of Queensland, School of Medicine
PO Box 789, Sanctuary Cove 4212

South Australia

Adelaide Training College of Complementary Medicine
Division 3/297 Montacute Rd, Newton 5074

Endeavour College of Natural Health
88 Currie Street, Adelaide 5000

University of South Australia, Division of Health Sciences
City East Campus, North Terrace, Adelaide 5000

Tasmania

Tasmanian Polytechnic (TAFE Tasmania)
75 Campbell Street, Hobart 7000

Victoria

Australasian College of Nutritional and Environmental Medicine (ACNEM)
10/23–25 Melrose Street, Sandringham 3191

Endeavour College of Natural Health (formerly known as Australian College of Natural Medicine)
City Campus: 368 Elizabeth St, Melbourne 3000

Holmesglen Institute of TAFE
585 Waverley Road, Glen Waverley 3150

National College of Traditional Medicine
1st Floor, 25–29 Devonshire Rd, Sunshine 3020

RMIT School of Health Sciences
Bundoora West Campus, Plenty Rd, Bundoora 3083

Southern School of Natural Therapies
39 Victoria St, Fitzroy 3065

Victoria University, Biomedical and Health Science Department
Ballarat Rd, Footscray 3011

Western Australia

Australian Institute of Holistic Medicine
862 North Lake Rd, Jandakot 6164

Endeavour College of Natural Health (formerly known as Australian College of Natural Medicine)
170 Wellington Street, East Perth 6004

Paramount College of Natural Medicine
11/15 Bonner Drive, Malaga 6090

COURSES IN NEW ZEALAND

Listed below are universities, schools and colleges in New Zealand offering undergraduate or postgraduate courses in nutritional medicine, herbal medicine, naturopathy or complementary medicine.

Bay of Plenty College of Homeopathy
2 Edgecombe Road, Tauranga, NZ 3110

Canterbury College of Natural Medicine
PO Box 4529, Christchurch, NZ 8140

Lotus Holistic Centre
1024 St Aubyn St West, Hastings, Hawkes Bay, NZ 4120

Naturopathic College of New Zealand Ltd
4–6 Lynton St, New Plymouth, NZ 4310

New Zealand School of Acupuncture and Traditional Chinese Medicine
Level 10, Willbank House, 57 Willis Street, Wellington, NZ 6011

South Pacific College of Natural Therapies
8 Arthur Street, Ellerslie, Auckland, NZ 1542

The International College of Herbal Medicine
18B Sirrah St, Okitu, Gisborne, NZ 4010

University of Canterbury (ENZAM New Zealand Centre for Evidenced Based Research into Complementary and Alternative Medicine)
Private Bag 4800, Christchurch, NZ 8140

Waikato Centre for Herbal Medicine Limited
PO Box 15064, Dinsdale, Hamilton, NZ 3243

Wellpark College of Natural Therapies
PO Box 78229, Grey Lynn, Auckland, NZ 1245

COMPLEMENTARY MEDICINE ASSOCIATIONS

Listed below are complementary medicine associations of Australian and New Zealand practitioners and industry.

Australia

Australasian Integrative Medicine Association (AIMA)
Royal Australian College of General Practitioners Building, 1 Palmerston Crescent, South Melbourne, VIC 3205
Chiefly represents medical doctors; however, other healthcare professionals may become associate members.

Australian Complementary Health Association
Ross House, 4th Floor, 247 Flinders Lane, Melbourne, VIC 3000
Represents consumers and practitioners.

Australian Natural Therapies Association (ANTA)
PO Box 657, Maroochydore, QLD 4558
Major association representing complementary medicine practitioners.

Australian Naturopathic Practitioners Association (ANPA)
Suite 36/123 Camberwell Road, East Hawthorn, VIC 3123
Longest-standing naturopathy association in Australia.

Australian Self Medication Industry (ASMI)
Level 22, 141 Walker Street, North Sydney, NSW 2060
Represents companies involved in the manufacture and distribution of over-the-counter consumer healthcare products; peak industry body for the Australia self-care industry.

Australian Traditional Medicine Society (ATMS)
12/27 Bank St, Meadowbank, NSW 2114
Currently Australia's largest professional association of complementary medicine practitioners

Complementary Healthcare Council (CHC)
Unit 2, 1 Napier Close, Deakin, ACT 2600
Peak body representing the complementary healthcare industry (suppliers, retailers, healthcare professionals and consumers).

Complementary Medicine Association (CMA)
Suite 1A, 126 Scarborough Street, Southport, QLD 4215

Federation of Natural and Traditional Therapists (FNTT)
PO Box 168, North Adelaide, SA 5006
Represents several professional associations.

International Aromatherapy and Aromatic Medicine Association
Level 1, 89/91 Burwood Road, Burwood, NSW 2136

National Herbalists Association of Australia (NHAA)
PO Box 45, Concord West, NSW 2138
Longest established association of Western herbal medicine practitioners

New Zealand

New Zealand Association of Medical Herbalists
PO Box 12852, Chartwell, Hamilton, NZ 3248

New Zealand Charter of Health Practitioners
344a Rosedale Road, Albany, North Shore, Auckland, NZ 0632
Represents 80% of total Natural Healthcare practitioner population of New Zealand.

New Zealand Natural Medicine Association
Private Box 303, 236 North Harbour, Auckland, NZ 0751

New Zealand Society of Naturopaths
PO Box 90–170, Victoria Street West, Auckland, NZ 1142

South Pacific Association of Natural Therapists
28 Willow Avenue, Birkenhead, Auckland, NZ 1310

MAJOR MANUFACTURERS OF HERBAL MEDICINES AND NATURAL SUPPLEMENTS

Australia

BioCeuticals
PO Box 6454, Alexandria, NSW 2015

Bio Concepts Pty Ltd
Unit 9/783 Kingsford Smith Drive, Eagle Farm, QLD 4009

DFC Thompson Australia Pty Ltd
23–25 Sefton Rd, Thornleigh, NSW 2120

Dr Vera's Pure Innovation
1800 625934

Eagle Pharmaceuticals
PO Box 927, Castle Hill, NSW 1765

Essential Nutrients Pty Ltd
107A Ledger Road, Beverley, SA 5009

FAB Health
PO Box 7962, Baulkham Hills BC, NSW 2153

Felton, Grimwald & Bosisto's Pty Ltd
61–81 Clarinda Road, Oakleigh South, VIC 3167

Interclinical Laboratories
Unit 6, 10 Bradford Street, Alexandria, NSW 2015

Lipa Pharmaceuticals Pty Ltd
21 Reaghs Farm Rd, Minto, NSW 2566

MediHerb Pty Ltd
PO Box 713, Warwick, QLD 4370

NPD
PO Box 1051, Eagle Farm, QLD 4009

Nutrition Care Pharmaceuticals Pty Ltd
PO Box 153, Dingley, VIC 3172

Olive Leaf Australia
767 Bischoffs Road, Coominya, QLD 4311

Tabco Pty Ltd
26 Roseberry St, Balgowlah, NSW 2093

The Herbal Extract Company of Australia
Unit 9/25 Childs Road, Chippington Norton, NSW 2170

VitaSearch
PO Box 7052, Alexandria, NSW 2015

New Zealand

Alpha Laboratories (NZ) Ltd
16–18 Bowden Road, Mt Wellington, Auckland, NZ 1060
Healtheries of Australia Pty Ltd
PO Box 22045, Otahuhu, Auckland, NZ 1640

RESOURCES USED TO COMPILE THIS BOOK

A book of this type requires careful research and access to quality resources in order to provide balanced and accurate information. Below is a list of many of the reference texts and electronic databases on which the information is based.

APPENDIX 5

GUIDE TO THE SAFE USE OF COMPLEMENTARY MEDICINES DURING THE PREOPERATIVE PERIOD

This table is intended to provide clinicians with some guidance when advising patients due for surgery about the safe use of complementary medicines (CMs). It is limited to the CMs reviewed in this book, especially those that are known or suspected to increase bleeding or interact with drugs commonly used in the perioperative period. The recommendations are conservative and not likely to be relevant to many low-risk or minor surgical procedures, but it is imperative that each patient be individually assessed before surgery.

CMs are listed alphabetically by common name. The comments section includes a brief description of the type of evidence available to support the recommendation; more detailed information is given in the individual monographs. Several different recommendations are possible. Sometimes there is a recommendation to suspend use 1–2 weeks before surgery, which should provide ample time for bleeding rates to return to normal or potential interactions to be avoided. This is most likely an overestimation of the actual time required. Please note that coumarin-containing and salicylate-containing herbs have not been included in the table unless they have demonstrated antiplatelet or anticoagulant effects in animal or human studies. Sometimes the recommendations are dose dependent; in other cases CM use appears safe but there is a theoretical concern.

It is acknowledged that, in practice, not all surgical patients will be able to follow these recommendations. In situations where bleeding would be a serious complication and a 1-week minimum deferment is not possible, tests of haemostasis prior to surgery should be considered.

It must be reiterated that the clinical relevance of some interactions and adverse effects is unknown and controlled studies in surgical patients are not available. However, it would seem prudent for healthcare providers to become familiar with these medicines, in order to advise patients appropriately and to anticipate, manage or avoid adverse events during the perioperative period.

Common name	Botanical name (where applicable)	Comments	Recommendation
Andrographis	*Andrographis paniculata*	Andrographolide inhibits platelet-activating-factor-induced platelet aggregation in a dose-dependent manner (confirmed clinically) (Amroyan et al 1999, Zhang et al 1994).	Suspend use 1 week before surgery.
Baical skullcap	*Scutellaria baicalensis*	There is a theoretical risk of anticoagulant activity; not observed in clinical trials.	Use under observation but likely to be safe.
Dong quai	*Angelica sinensis*	Dong quai has been found to have potent anticoagulant effects and haemostatic effects. Ferulic acid found in dong quai is reported to inhibit platelet aggregation. A case has been reported of subarachnoid haemorrhage with herbal combination red clover, Siberian ginseng and dong quai.	Suspend the use of high-dose supplements 1 week before surgery.

Common name	Botanical name (where applicable)	Comments	Recommendation
Evening primrose oil (EPO)	Omega-6 essential fatty acids or n-6 fatty acids	Gamma linolenic acid in EPO affects PG synthesis, leading to inhibition of platelet aggregation – clinical significance unknown.	Suspend use of high-dose concentrated products 1 week before surgery; however, safety is difficult to assess.
Feverfew	*Tanacetum parthenium*	Evidence is contradictory as to whether feverfew inhibits platelet aggregation Inhibition of platelet aggregation has been observed in several in vitro studies (Groenewegen & Heptinstall 1990, Marles et al 1992, Voyno-Yasenetskaya et al 1988); however, a small human study found no effects on platelet aggregation (Biggs et al 1982).	Use under observation but likely to be safe.
Fish oils	Omega-3 essential fatty acids or n-3 fatty acids	Multiple clinical studies conducted in surgical patients with no significant increase in bleeding observed (Harris 2007). Some benefits reported (see monograph). Bleeding times increased at very high doses of 12 g/day of n-3 fatty acids (Harris et al 1990).	Usual therapeutic doses are safe according to systematic review of use in surgical patients. Suspend use of high-dose products (12 g/day and higher) 1 week before surgery.
Garlic	*Allium sativum*	Inhibition of platelet aggregation is clinically significant — two cases of postoperative bleeding after excessive dietary intake have been reported (Burnham 1995, German et al 1995). One clinical study found reduced haematocrit values and plasma viscosity (Jung et al 1991).	Usual dietary intakes are likely to be safe. Suspend use of concentrated extracts (> 7 g) 1 week before surgery.
Ginger	*Zingiber officinale*	Standard intake likely to be safe. Oral doses of 4 g/day did not alter platelet aggregation or fibrinogen levels in one clinical study, whereas a high dose of 10 g/day significantly reduced platelet aggregation in another clinical study (Bordia et al 1997).	Usual dietary and therapeutic intakes are likely to be safe. Suspend use of high-dose (10 g/day) concentrated extracts 1 week before surgery.
Ginkgo	*Ginkgo biloba*	At least 10 clinical studies have found no significant effect on bleeding or platelets; however, rare cases of bleeding have been reported. One escalating dose study found that doses of 120 mg, 240 mg or 480 mg given daily for 14 days did not alter platelet function or coagulation (Bal Dit et al 2003).	Use under observation but likely to be safe.
Ginseng — Korean	*Panax ginseng*	Herb inhibits platelet aggregation according to both in vitro and animal studies, but clinical significance unknown. In contrast, the total saponin fraction has been shown to promote haemopoiesis by stimulating proliferation of human granulocyte-macrophage progenitors (Niu et al 2001).	Suspend use 1 week before surgery; however, safety is difficult to assess.
Ginseng — Siberian	*Eleutherococcus senticosus*	Siberian ginseng constituent 3, 4-dihydroxybenzoic acid has demonstrated antiplatelet activity in vivo.	Suspend use 1 week before surgery; however, safety is difficult to assess.
Goji	*Lycium barbarum*	Inhibition of platelet aggregation in vitro — clinical significance unknown. Not demonstrated in human studies.	Use under observation but likely to be safe.

Continued

Common name	Botanical name (where applicable)	Comments	Recommendation
Green tea	*Camellia sinensis*	Shown to exert antiplatelet aggregation and antithrombogenic activities. A case report of excessive daily intake 2.5–4.5 L/day decreased INR.	Usual dietary intake likely to be safe.
Guarana	*Paullinia cupana*	In vitro and in vivo research have identified antiplatelet activity (Bydlowski et al 1991).	Suspend use of concentrated extracts 1 week before surgery.
Kava kava	*Piper methysticum*	Increased sedation due to significant CNS-depressant effects possible. Inhibition of CYP2E1 has been demonstrated in vivo therefore serum levels of CYP2E1 substrates may become elevated (e.g. the anaesthetic drugs). • halothane • isoflurane • methoxyflurane	Use under professional supervision.
Licorice root	*Glycyrrhiza glabra*	Isoliquiritigenin inhibits platelet aggregation (Tawata et al 1992) and glycyrrhizin inhibits prothrombin (Francischetti et al 1997) according to in vitro tests – clinical significance unknown.	Usual dietary intakes likely to be safe. Concentrated extracts should be used with caution.
Meadowsweet	*Filipendula ulmaria*	In vitro and in vivo tests have identified anticoagulant activity (Liapina & Koval'chuk 1993) — clinical significance of these findings is unknown.	Suspend use of concentrated extracts 1 week before surgery.
Myrrh	*Commiphora molmol*	Guggul inhibits platelet aggregation in vitro and in a clinical study (Bordia & Chuttani 1979).	Suspend use of guggul preparations 1 week before surgery.
Policosanol		Doses of 10 mg/day and greater reduce platelet aggregation, according to clinical studies (Arruzazabala et al 2002, Castano et al 1999). Effect of 20 mg/day is similar to aspirin 100 mg stat.	Suspend use of doses 10 mg/day or greater 1 week before surgery.
Rosemary	*Rosmarinus officinalis*	Rosemary demonstrates antithrombotic activity in vitro and in vivo, possibly through inhibition of platelets. Clinical significance unknown.	Suspend use of concentrated extracts 1 week before surgery; however, clinical significance difficult to assess.
Shark cartilage		Substance displays anti-angiogenic properties, which could theoretically hinder healing.	Suspend use of supplement 1 week before surgery and until postoperative healing is complete (approx 6 weeks).
St John's wort	*Hypericum perforatum*	Use of herb for more than 2 weeks can induce pharmacokinetic interactions with CYP3A4 and P-gp substrates. This will result in reduced therapeutic responses to these drugs e.g. • alprazolam • cyclosporine • digoxin • midazolam • morphine • nortriptyline • warfarin	Use under professional supervision — if use is continued, drug doses may require modification. **Caution:** Withdrawal effects possible as SSRI-like activity is reduced and CYP and P-gp induction is removed — therapeutic failure of herb and possible drug toxicity.
Turmeric root	*Curcuma longa*	Curcumin inhibits platelet aggregation in vivo (Srivastava R et al 1985, 1986, Chen et al 2007) and in vitro (Srivastava KC 1989, Srivastava KC et al 1995, Jantan et al 2008). The anticoagulant effect of curcumin is weaker than that of aspirin — clinical significance unknown.	Usual dietary intakes likely to be safe. Suspend use of concentrated extracts 1 week before surgery.

Common name	Botanical name (where applicable)	Comments	Recommendation
Vitamin E	Alpha-tocopherol	Contradictory results have been obtained in clinical studies that have investigated whether vitamin E affects platelet aggregation or coagulation. A dose of 1200 IU/day (800 mg of D-alpha-tocopherol) taken for 28 days had no effects on platelet aggregation or coagulation, according to one clinical study (Morinobu et al 2002). Similarly, a second clinical study found the lower dose of 600 mg (900 IU) of RRR-alpha-tocopherol taken daily for 12 weeks did not alter coagulation activity (Kitagawa et al 1989). Alternatively, increased risk of gingival bleeding at doses of 50 mg/day was found by another study (Liede et al 1998).	Usual therapeutic doses are likely to be safe. Suspend use of high-dose supplements (> 1000 IU/day) 1 week before surgery; however, safety is difficult to assess.
Willow bark	*Salix* spp	Although it has been assumed that willow bark affects platelet aggregation owing to its salicylate content, one clinical study found that consumption of *Salicis cortex* (240 mg salicin daily) produced minimal effects on platelet aggregation (Krivoy et al 2001).	Use under observation but likely to be safe.

APPENDIX 6

CLINICAL USE AND SAFETY OF VITAMINS AND MINERALS

Clinical use and Safety of Vitamins						
Vitamin	**Australian and New Zealand RDI for adults (> 18 years)**	**Dose range used in practice**	**Major uses (oral or topical forms)**	**Cautions**	**Side effects**	**Toxicity**
A	Women: 700 μg Men: 900 μg	10,000–50,000 IU/day orally in divided doses Not recommended for more than 2 weeks without medical supervision	• Treating deficiency • Prevention of secondary deficiency (e.g. coeliac disease, cystic fibrosis, pancreatic disease) • Reducing severity of infectious diseases in children • Dermatology — many uses • Adjunct to chemotherapy • Slowing progression of retinitis pigmentosa • Osteoporosis • Anaemia	• Hypersensitivity • Pregnancy • Hypervitaminosis A • Retinoid analogue use • Lactation • Chronic renal failure or liver disease	**Early signs** • Dry rough skin and mucous membranes, desquamation • Coarse sparse hair, alopecia of eyebrows • Diplopia • Bone and joint pain **Later signs** • Irritability • Increased intracranial pressure and headache • Dizziness • Hepatotoxicity	• Cumulative toxicity if > 100,000 IU long term • Acute toxicity possible if > 2,000,000 IU • The recommended adult daily amount of vitamin A from all sources in 2500 IU. Taking more than 8000 IU a day during pregnancy may cause birth defects.
B_1 (thiamin)	Women: 1.1 mg Men: 1.2 mg	5–3000 mg	• Treating deficiency • Prevention of secondary deficiency (e.g. hyperemesis and malabsorption states) • Acute alcohol withdrawal • Alzheimer's dementia • Dysmenorrhoea • Congestive heart failure • Diabetes	• Hypersensitivity	Well tolerated	Non-toxic
B_2 (riboflavin)	Women: 1.1 mg (< 70 yrs: 1.3 mg) Men: 1.3 mg (>70 yrs: 1.6 mg)	10–400 mg/day	• Treating deficiency • Prevention of secondary deficiency (e.g. chronic diarrhoea, liver disease, chronic alcoholism) • Prevention of migraine headaches • Reducing incidence of both nuclear and cortical cataract • Wound healing • Pyridoxine metabolism • Breast cancer adjunct to Tamoxifen	• Hypersensitivity	Generally well tolerated, but rare side effects include diarrhoea and polyuria.	Non-toxic

B_3 (niacin)	Women: 11 mg Men: 12 mg	1500–2000 mg crystalline niacin or sustained-release forms daily	• Treating deficiency • Pellagra • Prevention of secondary deficiency (e.g. anorexia nervosa) • Hypercholesterolaemia and hypertriglyceridaemia • Syndrome X • Tryptophan deficiency • Diabetes	• Hypersensitivity • Diabetes • Peptic ulcer disease • Gout • Hepatitis • Liver function should be monitored and patients observed for symptoms of myopathy.	• Flushing is a common side effect (not with nicotinamide). Night-time administration, extended-release (ER) niacin or concurrent administration of aspirin can reduce these effects. • Palpitations, chills, pruritus, GIT upset and cutaneous tingling.	• Tachycardia, chills, sweating, shortness of breath, nausea, vomiting, myalgias, hepatotoxicity • ER niacin is considered the safest form.
B_5 (panto-thenic acid)	Women: 4 mg/day Men: 6 mg/day	200–300 mg/day	• Deficiency rare • Prevention of secondary deficiency (e.g. malabsorption syndrome, alcoholism, diabetes, OCP and IBD) • Enhanced wound healing • Hypercholesterolaemia • Prevention of NTD • Female alopecia		Well tolerated • Contact dermatitis from topical application	No toxicity level known
B_6 (pyridoxine)	Women: 1.3 mg (> 50 yrs: 1.5 mg) Men: 1.3 mg (> 50 yrs: 1.7 mg)	5–1200 mg/day	• Treating deficiency • Prevention of secondary deficiency (e.g. malabsorption syndromes, cancer, liver cirrhosis and alcoholism, hyperthyroidism) • Relieving symptoms of PMS and morning sickness • Leg cramps of pregnancy • Hyperhomocysteinaemia (often with folic acid and vitamin B_{12}) • Reducing thromboembolism • Improved outcomes after heart transplant • Reducing repeated febrile convulsions in children • Autism (with magnesium) • Stress	• Hypersensitivity • Long-term use of high-dose pyridoxine supplements (> 100 mg, although this level varies between individuals) should be used with caution.	• Nausea, vomiting, headache, paraesthesias, sleepiness and low serum folic acid levels have been reported. • If taken at night, may induce vivid dreams.	• Paraesthesia, hyperaesthesia, bone pain, muscle weakness, numbness and fasciculation most marked at the extremities • Unsteady gait, numbness of hands and feet, impaired tendon reflexes. • Excess doses of B_6 can cause degeneration of the dorsal root ganglia in the spinal cord, loss of myelination and degeneration of sensory fibres in the peripheral nerves.

Continued

Clinical use and Safety of Vitamins *continued*						
Vitamin	**Australian and New Zealand RDI for adults (> 18 years)**	**Dose range used in practice**	**Major uses (oral or topical forms)**	**Cautions**	**Side effects**	**Toxicity**
			• Cognitive performance/ Alzheimer's disease • Schizophrenia • Tardive dyskinesia • Parkinson's disease			• Dose and time frame at which toxicity occurs varies significantly between individuals. • Studies involving large populations found minimal or no toxicity with 100–150 mg/day over 5–10 years, whereas women self-medicating for PMS taking 117 ± 92 mg for 2.9 ± 1.9 years have reported increased incidence of peripheral neuropathy.
B_{12} (cobalamin)	Adult > 13 years: 2.4 μg/day	0.5–2000 mg/day	• Treating deficiency: primary deficiency (vegans and vegetarians, breast-fed infants of vegetarian mothers, elderly patients and alcoholics) • Prevention of secondary deficiency (e.g. atrophic gastritis, achlorhydria, pancreatic insufficiency, Crohn's disease, bacterial or parasitic infestations) • Pernicious anaemia • Hyperhomocysteinaemia (with B_6 and folate) • Cardiovascular protection • Prevention of NTD • Recurrent abortion • Depression • HIV infection • Cognitive impairment • Diabetic retinopathy • Sleep disorders • Tinnitus • Multiple sclerosis • Amyotrophic lateral sclerosis	• Hypersensitivity • Avoid in cases of altered cobalamin metabolism or deficiency associated with chronic cyanide intoxication.	None known	Well tolerated

Folate	Adults: 400 μg/day Up to 1 mg/day in deficiency states	1–30 mg/day	• Treating deficiency • Prevention of secondary deficiency (e.g. malabsorption syndromes such as coeliac and Crohn's disease, HIV infection), MTHFR gene polymorphism • Preconception care and pregnancy (prevention of neural tube defects) • Hyperhomocysteinaemia • Cardiovascular disease protection • Cognitive impairment • Anticonvulsant-induced folate deficiency • Depression • Schizophrenia • Reducing incidence of cancer • Periodontal disease • Vitiligo • Topical: periodontal disease	• Hypersensitivity • Use may mask B_{12} deficiency by correcting the apparent microcytic anaemia without altering the potential for or progression of neurological damage.	Doses > 5 mg/day: generalised urticaria, nausea, flatulence and bitter taste in the mouth, and some CNS activation in the form of irritability and excitability, altered sleep pattern.	Non-toxic
C	45 mg	250–12,000 mg/day orally in divided doses More used when administered IV	• Treating deficiency • Prevention of secondary deficiency (e.g. heavy smokers, achlorhydria, chronic diarrhoea, major surgery) • Treating iron deficiency anaemia (with iron) • Prevention and treatment of common URTI such as colds and influenza and mild allergic responses • Prevention and adjunctive treatment of cardiovascular disease and cancer • Management of diabetes and asthma • Atopy • Prevention of cataracts • Male infertility • Adjunct for haemodialysis patients	• Hypersensitivity • Increases iron, and decreases copper, absorption • Glucose-6-phosphate dehydrogenase deficiency • Haemochromatosis • Thalassaemia major • Sideroblastic anaemia • Renal impairment • Interacts with numerous laboratory tests (e.g. serum cholesterol and triglycerides and urinary oxalate; refer to monograph)	• None expected if < 3000–4000 mg/day, but this varies between individuals • Gastrointestinal upset: nausea, diarrhoea, flatulence, distension • Hyperoxaluria and renal stones now considered doubtful	Considered non-toxic

Continued

Clinical use and Safety of Vitamins *continued*						
Vitamin	**Australian and New Zealand RDI for adults (> 18 years)**	**Dose range used in practice**	**Major uses (oral or topical forms)**	**Cautions**	**Side effects**	**Toxicity**
			• Oral and topical forms used for various dermatological conditions (e.g. wound healing, photo-aged skin, prevention of sunburn (with vitamin E))			
D	Children & adults < 50 yrs: 200 IU/day Adults 51–70 yrs: 400 IU/day Adults > 70 yrs: 600 IU/day	400–300,000 IU/day	• Treating deficiency • Inadequate sun exposure or poor dietary intake • Prevention of secondary deficiency (e.g. malabsorption states) • Hypoparathyroidism (with calcium) • Hypophosphataemia (with phosphorus) • Prevention of bone fracture and osteoporosis (with calcium) • Hepatic and renal osteodystrophy • Scleroderma • Cancer • Diabetes • Prevention and treatment of infections • Depression • Multiple sclerosis • Lupus	• Hypersensitivity • Hypercalcaemia • Sarcoidosis • Hyperparathyroidism • SLE • Vitamin D toxicity • Pregnancy • Lactation • Renal failure • Use of cardiac glycosides, thiazide diuretics, calcium-channel blockers	• Not seen with doses < 2400 IU/day • Doses > 3800 IU: hypercalcaemia, soft tissue calcification • Fatigue, headache, nausea, vomiting, metallic taste, abdominal cramps, myalgia, tinnitus, arthralgia, constipation, polyuria, polydipsia	• Cumulative toxicity possible • Between 50,000 and 100,000 IU/day: signs of hypercalcaemia • 50,000–200,000 IU/day: nausea, vomiting, anorexia, polyuria, muscle pain • Calcification of soft tissue and organs, cardiac arrhythmias • Toxic levels cannot be obtained from sun exposure.

E	Women: 7 mg alpha-tocopherol Men: 10 mg alpha-tocopherol	50–3200 IU/day	• Treating deficiency • Prevention of secondary deficiency (e.g. malabsorption syndromes, cystic fibrosis) • Prevention of cardiovascular disease, certain cancers, ischaemic stroke in high-risk hypertensive patients, nitrate tolerance • Enhancing immune function in the elderly • Reducing incidence of common cold • Slowing progression of Alzheimer's dementia • Improving symptoms in PMS, dysmenorrhoea, menopause, intermittent claudication • Reducing pain in OA and RA • Cancer • Age-related macular degeneration • Huntington's disease • Treating some forms of male infertility • Oral and topical use for many dermatological states • Scar tissue • Prevention or treatment of many other conditions, such as exercise-induced tissue damage, some types of senile cataracts, epilepsy and fibromyalgia	• Hypersensitivity • People with impaired coagulation, inherited bleeding disorders, history of haemorrhagic stroke, vitamin K deficiency or at risk of pulmonary embolism or thrombophlebitis • Suspend use of supplements 1–2 weeks before major surgery.	• Adverse effects are dose-related and tend to occur only at very high doses (> 1200 IU/day) • Side effects include diarrhoea, flatulence, nausea and heart palpitations • Increased risk of bleeding if vitamin K deficiency present	Vitamin E is relatively non-toxic. Doses as high as 3200 mg/day have been used for 12 years without signs of toxicity.

Continued

CLINICAL USE AND SAFETY OF MINERALS *continued*

Mineral	Australian and New Zealand RDI for adults (> 18 years)	Dose range used in practice	Major uses (oral or topical forms)	Cautions	Side effects	Toxicity
Calcium	Adults: < 70 yrs: 1000 mg/day > 70 yrs: 1300 mg/day	100–2000 mg/day	• Treating deficiency • Prevention of secondary deficiency (e.g. achlorhydria and malabsorption syndromes), more common in elderly • Prevention of osteoporosis, pre-eclampsia, maintenance of bone density, colorectal cancer • Symptoms of PMS • Hypertension and hyperlipidaemia • Dyspepsia • Weight loss • Nephrolithiasis • Dry eye	• Hypersensitivity • Hyperparathyroidism • Hypercalcaemia • Renal impairment or kidney disease • Sarcoidosis or other granulomatous diseases only under medical supervision	Gastrointestinal discomfort, nausea, loss of appetite, constipation, flatulence, metallic taste, muscle weakness	• Increased serum calcium level may be associated with hypotonia, depression, lethargy and coma. • Prolonged hypercalcaemic state, especially if normal or elevated serum phosphate, can precipitate ectopic calcification of blood vessels, joints, gastric mucosa, cornea and renal tissue.
Chromium	Women: 25 μg Men: 35 μg	50–1000 μg	• Treating deficiency • Diabetes • Hypoglycaemia • Hyperlipidaemia • Obesity • Atypical depression • Polycystic ovary syndrome • Syndrome X • Exercise aid • Prevention of myocardial infarction	Hypersensitivity	• Irritability and insomnia have been reported with chromium yeast supplementation. • Chromium picolinate is well tolerated.	Chromium IV is used in industry and is highly toxic, whereas Cr III, which is used in supplements, is well tolerated.
Iodine	Adults: 150 μg/day	0.5–6 mg	• Treating deficiency • Secondary deficiency (high consumption of goitrogens combined with low iodine intake) • Preventing deficiency in high-risk groups including in utero, pregnancy, infancy • Prevention of ADHD • Fibrocystic breast disease • Breast cancer • Mastalgia	• Hypersensitivity • Thyroid conditions	Symptoms of iodine hypersensitivity are fever, painful joints, lymph node enlargement, eosinophilia, urticaria, angio-oedema, cutaneous and mucosal haemorrhage and fatal peri-arteritis.	• Chronic iodine toxicity when intake is > 2 mg/day. Symptoms: brassy taste in mouth, burning sensation in mouth and throat, increased salivation, gastric irritation, abdominal pain, nausea, vomiting and diarrhoea • Acneiform skin lesions, pulmonary oedema, depression • Chronic ingestion > 500 μg/day by children → increased thyroid size

Iron	Women: 19 to menopause: 18 mg Post-menopause: 8 mg Men: 8 mg	10–100 mg/day	• Treating deficiency • Prevention of secondary deficiency (e.g. menorrhagia, cystic fibrosis) • Unexplained fatigue without anaemia • Improving athletic performance • Pregnancy • Postpartum anaemia • Cognitive function • ADHD	• Hypersensitivity • Haemochromatosis • Haemosiderosis • Iron-loading anaemias (thalassaemia, sideroblastic anaemia) • Liquid iron preparations can discolour teeth (brush teeth after use).	• Gastrointestinal disturbances such as nausea, diarrhoea, constipation, heartburn, upper gastric discomfort • Preliminary evidence indicates iron may be implicated in the pathogenesis of various disease states. Therefore, supplementation is indicated only with demonstrated biological need.	Haemochromatosis can develop from long-term excessive intake Iron toxicity causes severe organ damage and death. The most pronounced effects are haemorrhagic necrosis of the gastrointestinal tract and liver damage.
Magnesium	Women: 310 mg > 30 yrs: 320 mg Men: 400 mg > 30 yrs: 420 mg	200–1200 mg/day	• Treating deficiency • Prevention of secondary deficiency (e.g. inflammatory bowel diseases, diabetes, hyperthyroidism, elevated cortisol) • Alleviating symptoms of coronary heart disease, reducing hypertension, reducing plasma lipid levels, reducing incidence of arrhythmias in congestive heart failure • Prevention of migraine headache, premenstrual headache, PMS, dysmenorrhoea, osteoporosis • ADHD, autism spectrum disorders • Kidney stone prevention • Asthma • Diabetes • Dyspepsia • Constipation • Chronic leg cramps • Leg cramps in pregnancy	• Hypersensitivity • Renal failure and heart block (unless pacemaker present)	**Most common** • Diarrhoea and gastric irritation; usually not seen at doses < 350 mg/day (elemental) • Doses of inorganic magnesium > 350 mg/day may be associated with adverse effects. Dividing doses will maximise bioavailability and reduce side effects. • Overuse of magnesium hydroxide or magnesium sulfate may cause deficiencies of other minerals or lead to toxicity. **Other side effects** Decreased heart rate, hypotension, muscle weakness	Most commonly seen in patients with renal insufficiency. Symptoms: muscle weakness, sedation, ECG changes, confusion, hypotension

Continued

CLINICAL USE AND SAFETY OF MINERALS *continued*

Mineral	Australian and New Zealand RDI for adults (> 18 years)	Dose range used in practice	Major uses (oral or topical forms)	Cautions	Side effects	Toxicity
Selenium	Women: 60 μg Men: 70 μg	80–200 μg/day	• Treating deficiency • Prevention of secondary deficiency (e.g. cirrhosis, malabsorption syndromes, cystic fibrosis, coeliac, disease, HIV infection) • Reducing total cancer incidence and mortality (especially lung, colorectal and prostate cancers), adjunctive treatment • HIV infection • Cardiovascular disease • Autoimmune thyroiditis • Diabetes • Symptoms of RA, asthma • Male infertility • Immune enhancement • Anxiety and depression • Reducing morbidity in preterm infants	• Hypersensitivity • NHMRC upper level of intake is 400 μg/day	• Nausea, vomiting, nail changes, irritability, fatigue • Organic form of selenium found in high-selenium yeast is less toxic and safer than other forms.	Long-term use of excessive doses (> 1000 μg/day) can produce fatigue, depression, arthritis, hair or finger-nail loss, garlicky breath or body odour, gastrointestinal disorders and irritability.
Zinc	Women: 8 mg/day Men: 14 mg/day	25–200 mg/day	• Treating deficiency • Prevention of secondary deficiency (e.g. cirrhosis, malabsorption syndromes, severe burns, major surgery) • Treating the common cold and reducing symptoms • Age-related macular degeneration • Diabetes • Enhancing wound healing (e.g. leg ulcers)	• Hypersensitivity	Mild gastrointestinal upset at doses of 50–150 mg/day	• Single doses of 225–450 mg usually induce vomiting • Nausea, vomiting, diarrhoea, fever and lethargy have been observed after ingestion of 4–8 g. • Doses ranging from 100 to 150 mg/day interfere with copper metabolism and cause hypocupraemia, red blood cell microcytosis, and neutropenia if used long term.

			• Decreasing relapse rates in Crohn's disease • Decreasing incidence of pneumonia • Arterial and venous leg ulcers • Male infertility • Impotence • ADHD • Depression • Diarrhoea • Anorexia nervosa • Tinnitus • Warts • Acne vulgaris • Topical: herpes simplex infection			

Note

Mutivitamins. Overall, acute toxicity is unlikely with combination vitamin supplements unless huge amounts have been ingested. In the case of toxicity or side-effects, signs and symptoms will relate to the individual nutrient ingested. In general, gastrointestinal symptoms such as discomfort, nausea and diarrhoea are the most frequent adverse effects.

Special care. Of all the nutrients listed, extra special care must be taken when supplementing with vitamins A and D and the mineral iron. The forms of selenium and niacin used in practice also have a major influence on their safety profile and should be taken into consideration.

RDI. For more details regarding RDI for specific age groups: www.nhmrc.gov.au/publications/synopses/n35syn.htm

APPENDIX 7

EVIDENCE BASE FOR PHYSIOLOGICAL ACTIVITIES OF HERBS AND SUPPLEMENTS

Evidence codes

AS Animal studies

CT Clinical trial

EP Based on epidemiological studies

IV In vitro studies

PH Based on known pharmacological activity of constituents

TH Theoretical

TU Traditional use

Assumptions made when collating the information for this table

- Information is compiled from the 130 monographs included in this book.
- All information refers to oral dose forms unless otherwise specified.
- Information listed here is correct at the time of writing; however, because of the ever-expanding knowledge base in this area, new research is constantly being published.
- Not all actions referred to in the text are covered; see monographs for more detail.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
Adaptogenic			
	Brahmi	IV, AS	
	Ginseng — Korean	AS, CT	Thought to influence hypothalamic–pituitary–adrenal axis.
	Ginseng — Siberian	IV, AS, CT	Appears to alter the levels of different neurotransmitters and hormones involved in the stress response chiefly at HPA axis.
	Rhodiola	AS, CT	Found to prevent catecholamine release.
	Shatavari	TU, AS	
	Tyrosine	CT	Appears to enhance release of catecholamines during stress.
	Withania	AS	Suppresses stress-induced increases in dopamine receptors and acts as a GABA-mimetic agent; ability to reduce adrenal weight and plasma cortisol levels.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
Analgesic			
	Brahmi	AS	Antinociceptive activity identified when used in combination with other herbs.
	Chondroitin	CT	Musculoskeletal pain.
	Clove oil	AS, CT	Effects due to the eugenol, beta-caryophyllene component; clinical trials used tiger balm.
	Dandelion (root)	AS	Mild effects reported.
	Devil's claw	CT, AS	Opioid system involved in the antinociceptive effects.
	Eucalyptus	AS	Central and peripheral effects attributed to monoterpene components.
	Evening primrose oil	PH	
	Fenugreek	AS	Antinociceptive activity identified.
	Feverfew	AS, CT	Inhibits prostaglandin production and acts at nociceptors.
	Ginger	CT	Inhibits prostaglandin and thromboxane production and topically depletes substance P.
	Ginseng — Korean	AS	Potentiates opioid-induced analgesia.
	Glucosamine	CT	Musculoskeletal pain — effects seen in osteoarthritis.
	Kava kava	IV, AS	Local anaesthetic.
	Lemon balm	IV, AS	High doses.
	Meadowsweet	TH	Based on its high salicylate content.
	Noni	AS	Opioid-like properties, dose-dependent analgesic properties.
	Peppermint oil	CT	Observed for oil applied topically.
	St John's wort	IV, AS	Binds opioid receptors and modulates COX-2 expression.
	SAMe	CT	Musculoskeletal pain — effects seen in osteoarthritis (not prostaglandin mediated).
	Shark cartilage	AS	Multiple mechanisms.
	Stinging nettle	CT	Probably due to counter-irritant effect.
	Vitamin E	CT	Most likely mediated via inhibitory effects on COX-2 and 5-lipooxygenase.
	Willowbark	CT	Musculoskeletal pain.
Antacid			
	Magnesium	TU	
	Meadowsweet	TU	
Anthelmintic			
	Thyme	IV	Thymol possesses antihelmintic activity.
Anti-allergic			
	Adhatoda	IV, AS	Asicine and vasicinone possess bronchodilatory activity and inhibit allergen-induced bronchial obstruction, with effects comparable to those of sodium cromoglycate.
	Albizia	IV, AS	Significant mast-cell-stabilisation effects, similar to those of sodium cromoglycate. Recent comparative study found albizia leaf, albizia stem and bark, and disodium chromoglycate to be equally potent on mast cell stabilisation.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Baical skullcap	IV, AS	Baicalein has been shown to inhibit IgE antibody-mediated immediate and late phase allergic reactions; inhibited IgE-mediated TNF-alpha and IL-6 production from mast cells; suppressed leukotriene C4 release by polymorphonuclear leucocytes. Baicalin 5-10-fold more potent than azelastine.
	Brahmi	IV	Potent mast-cell-stabilising activity (methanolic fraction) comparable to that of disodium cromoglycate.
	Clove oil	IV, AS	Inhibits histamine release.
	Feverfew	IV, AS	Inhibits histamine release (different mechanism to cromoglycate); constituent parthenolide significantly inhibits IgE-antigen-induced mast cell degranulation.
	Ginger	IV	Dose-dependent inhibition of drug-induced histamine release.
	Ginseng — Korean	IV	Stabilises cell membrane.
	Ginseng — Siberian	IV	Inhibits histamine release, tumour necrosis factor-alpha and IL-6.
	Hops	AS	Inhibits histamine release.
	Licorice	AS	Relieves IgE-induced allergic reactions.
	Peppermint	IV, AS	Inhibits histamine release.
	Perilla	IV, AS, CT	Inhibits histamine release, down-regulates Th2-type cytokine production, suppresses IgE and IgG antibodies and IL-4, IL-5 and IL-10.
	Probiotics	CT	Reduces antigen transport through the intestinal mucosa.
	Quercetin	IV, AS	Stabilises mast cells, neutrophils and basophils.
	St Mary's thistle	IV, AS	Mast-cell stabilisation.
	Stinging nettle	CT	Freeze-dried preparation showed activity.
	Vitamin C	CT	Reduces histamine levels.
Anti-anxiety/anxiolytic			
	Baical skullcap	IV, AS	Certain constituents bind with the benzodiazepine-binding site of the GABA-A receptor.
	Chamomile	AS	Binds benzodiazepine receptors.
	Ginger	AS	In combination with ginkgo biloba.
	Ginseng — Korean	IV, AS	Regulates GABA-A receptors in vitro.
	Kava kava	CT	Various mechanisms.
	L-Lysine	CT	5-HT_4 receptor antagonist and benzodiazepine receptor agonist.
	Lavender oil	AS, CT	Induces relaxation and sedation.
	Lemon balm	AS, CT	Eugenol and citronellol bind to GABA-A receptors and increase the affinity of GABA to receptors.
	Passionflower	AS, CT	Unknown mechanism — possibly acts via GABA.
	Quercetin	AS	Mechanisms unknown.
	St John's wort	IV, AS	Various mechanisms — possibly acts via GABA.
	Sage oil	IV	Compounds in methanolic extract have affinity for benzodiazepine receptors.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Valerian	IV, AS, CT	Stimulates the release of GABA, inhibits GABA reuptake and may have an effect at GABA receptors; low-dose valerian (100 mg) reduces situational anxiety without causing sedation.
	Withania	AS, CT	Exerted by constituent glycowithanolides.
Anti-atherogenic — See listing under Lipid-lowering			
Antibacterial — See listing under Antimicrobial			
Anti-catarrhal			
	Eucalyptus	CT	Decreased nasal congestion
	Horseradish	TU	Eliminates respiratory tract catarrh
Anticancer (e.g. antimutagenic, antineoplastic and/or anti-angiogenic activity has been identified)			
	Andrographis	IV	Increases apoptosis of prostate cancer cells; decreased proliferation of human cancer cells.
	Astragalus	IV, AS, CT	Tested in combination with other herbs.
	Baical skullcap	IV, AS	Baicalein, baicalin and wogonin shown to induce apoptosis, inhibit proliferation, prevent metastases and inhibit angiogenesis; *S. baicalensis* demonstrated dose-dependent inhibition of squamous cell carcinoma, breast cancer, hepatocellular carcinoma, prostate carcinoma and colon cancer cell lines.
	Bilberry	IV, AS	Anticarcinogenic and anti-angiogenic activity; inhibition of nuclear factor-kappa B activation pathway.
	Chamomile	IV, AS	Apigenin has been shown to inhibit carcinogenesis in a variety of experimental models.
	Cinnamon	IV	Antitumour activity.
	Cranberry	IV	Due to proanthocyanidins.
	Creatine	AS	Antitumour.
	Clove oil	IV	Demonstrated anticancer apoptosis activity constituent eugenol.
	Dandelion	IV	Anti-angiogenic.
	Dong quai	IV	Anti-tumour effects.
	Dunaliella salina	IV	Antiproliferative.
	Echinacea	IV	Induces apoptosis.
	Fenugreek	IV, AS	Antineoplastic; induced apoptosis in vitro to breast, pancreatic and prostate cancer.
	Flaxseed oil	PH	ALA demonstrated to inhibit tumour progression.
	Garlic	IV, AS	Various mechanisms; antineoplastic in breast, prostate, endometrial, stomach and colon cancer.
	Ginkgo	IV, AS	Antioxidant, anti-angiogenic and gene-regulating activity.
	Ginseng — Korean	IV, AS	Antitumour, antimetastatic, induces apoptosis and is radioprotective.
	Goldenrod	IV, AS	Antineoplastic activity demonstrated against prostate, breast, small-cell lung carcinoma and melanoma cancer cell lines in vitro; prostate cancer cell in vivo.
	Goldenseal	IV, AS	Demonstrated for the berberine constituent.
	Grapeseed extract	IV, CT	Suppresses tumour growth and has cytotoxic activity against a range of cancer cells, including breast, lung, prostate, and gastric adenoma cells.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Green tea	IV, EP	Reduction in proliferation, increase in apoptosis and possible anti-angiogenic properties identified; supported by epidemiological studies.
	Horseradish	PH	Antitumour.
	Lavender	IV, AS, PH	Preliminary evidence of activity for several constituents.
	Lavender oil	IV, AS	Antineoplastic in cancer of the colon, liver, lung, breast, pancreas, prostate, as well as melanoma.
	Licorice	IV, AS	Antitumour, anti-angiogenic, cell-cycle arrest and induces apoptosis.
	Lutein	CT	Possibly endometrial, lung, breast, bowel.
	Mullein	IV	Antitumour.
	Noni	IV, AS	Antitumour, antiproliferative and induces apoptosis.
	Oats		Anticytotoxic, antimutagenic, antitumourogenic.
	Perilla	IV, AS	Multiple mechanisms involved.
	Quercetin	IV, AS	Multiple mechanisms involved.
	Red clover	IV, AS, CT	Antimutagenic, antiproliferative and anti-angiogenic in vitro as well as protecting against chemical-induced DNA damage.
	Red yeast rice	ES	Antitumour.
	Rhodiola	IV, AS	Animutagenic, cytostatis, antiproliferative and antimetastatic.
	St John's wort	IV, AS	Selective photosensitisation of tumour cells; antineoplastic, anticarcinogenic, antiproliferant, proapoptotic, antiinvasive and antimetastatic effects.
	St Mary's thistle	IV, AS	Anti-angiogenic and antitumour.
	Saw palmetto	IV	Prostate cancer cell lines.
	Schisandra	IV	Anticancer activity demonstrated against leukaemia, lung and hepatocellular cancer cells in vitro.
	Shark cartilage	IV, AS	Anti-angiogenic and antitumour.
	Shatavari	AS	
	Soy	IV, ES AS	Multiple mechanisms attributed to phyto-oestrogen and isoflavone content. Activity shown against breast and prostate cancers.
	Turmeric	IV, AS, CT	Promotes apoptosis, reduces proliferation, reduces angiogenesis and metastases.
	Vitamin A	CT	Stimulates epithelial cell differentiation, preventing the proliferation of dedifferentiated or undifferentiated carcinoma cells in skin, breast, liver, colon, cervical, prostate, oral, pharyngeal, oesophageal and lung carcinomas.
	Vitamin B_6	IV	Antitumour on cell lines including breast and pituitary cells.
	Vitamin D	IV	
	Withania	IV, AS	Antineoplastic, anti-angiogenic and enhances apoptosis.
Chemoprotection			
	Beta-carotene	EP, AS	Effect associated with 'natural' beta-carotene and natural sources. Mechanisms proposed include antioxidant activity, stimulation of gap junction communication, inhibition of cell proliferation and oncogene expression.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Calcium	CT	Prevention of colorectal cancer and recurrence of adenomatous polyps.
	Celery	AS	May reduce incidence of stomach, colon, liver and lung cancer
	Dunaliella salina	IV	Effects associated with 'natural' beta-carotene component.
	Echinacea	AS	Reduces tumour incidence.
	Feverfew	IV, CT	Attributed to constituent parthenolide, which inhibits cell cycle, promotes cell differentiation and induces apoptosis; breast, cervical, prostate cancers.
	Fish oils	IV, AS	Demonstrated actions include suppression of neoplastic transformation, cell growth inhibition, enhanced apoptosis and anti-angiogenicity; especially breast, prostate and colorectal cancers.
	Flaxseed oil	CT	Increased levels of ALA associated with reduced risk of breast cancer.
	Folate	EP, AS, CT	Especially cervix, colorectal, lung, oesophagus, brain, pancreas and breast cancers.
	Garlic	IV, AS	Various mechanisms.
	Ginger	IV, AS	Antitumour properties partly due to antioxidant and anti-inflammatory effect; breast, ovarian, gastric and pancreatic cancers.
	Ginkgo	AS	
	Ginseng — Korean	IV, AS, CT	Various mechanisms.
	Guarana	AS	Reduces cellular proliferation of preneoplastic cells.
	Hops	IV	Component chalcone, xanthohumol prevents angiogenesis in vivo.
	Horse chestnut	AS, IV	Inhibits cell proliferation and induces apoptosis.
	Lutein and zeaxanthin	EP	Various cancers.
	Lycopene	IV, AS, CT	Thought to inhibit proliferation of cancer cells by initiating cell-cycle arrest and apoptosis; especially prostate, stomach and cervical cancers.
	Olive	IV	Anticarcinogenic, antimetastatic, antimutagenic and anti-angiogenic.
	Prebiotics	IV, AS	Anti-cancer effects.
	Probiotics	IV, AS, CT	Antimutagenic, anticarcinogenic (e.g. nitrosamines), immune enhancing.
	Pygeum	IV, AS	Regulation of cancer cell growth in vitro and in vivo; against prostate cancer.
	Rosemary	IV, AS, TU	
	St Mary's thistle	AS, IV	
	Selenium	CT, EP	Significantly reduces total cancer mortality, total cancer incidence and incidence of lung, colorectal and prostate cancers.
	Stinging nettle	IV, CT	Antiproliferative in prostate cells.
	Turmeric	AS, CT	Against skin, stomach, colon, prostate, breast and oral cancer.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Vitamin A	IV, AS	Deficiency can induce metaplastic changes to epithelial cells; retinoic acid thought to act as inhibitor of carcinogenesis.
	Vitamin B_3	IV, AS	Dietary niacin status potentially affects DNA repair, genomic stability and immune function influencing cancer risk.
	Vitamin C	EP, IV	Mechanisms largely unknown.
	Vitamin D	EP, CT	Demonstrated reduction of incidence of all cancers.
	Vitamin E	EP	
	Withania	IV, AS	Multiple mechanisms.
	Zinc	EP	
Antifibrotic			
	Baical skullcap	IV, AS	In combination; chemopreventive role in the development of hepatocellular carcinoma.
	Ginger	CT	
	St Mary's thistle	AS	Against liver fibrosis.
Radioprotective			
	Ginseng — Korean	IV, AS	
	Hawthorn	IV	
	Peppermint	AS	Exerted through antioxidant and free-radical scavenging activities.
Anticoagulant — See listing under Blood thinning			
Anticonvulsant			
	Albizia	AS	
	Baical skullcap		Constituent wogonin exhibits anticonvulsive effects mediated by GABA.
	Devil's claw	AS	Anticonvulsive action through GABAergic neurotransmission.
	Ginseng — Korean	AS	
	Lavender oil	AS	
	Passionflower	IV	Action through GABAergic and opioid pathways.
	Withania	AS	Likely due to GABA-A modulation.
Antidepressant/neurotransmitter effects			
	Albizia	AS	Influences GABA, serotonin and dopamine levels.
	Brahmi	AS	Mechanism unknown.
	Chromium	AS	Various mechanisms.
	Fish oil	CT	Various mechanisms.
	Folate	CT	Effectiveness may be restricted to those patients with an existing deficiency.
	Ginkgo biloba	IV, AS	May inhibit MAO-A; increases uptake of serotonin; direct and indirect cholinergic activity; competitive antagonist for GABA-A receptors; moderation of corticosterone levels.
	Licorice	IV	Inhibits serotonin reuptake; effect upon norepinephrine and dopamine.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Perilla	AS	Mechanism unknown — possibly through cell proliferation in the hippocampus.
	Rhodiola	IV	Various mechanisms.
	St John's wort	CT	Various mechanisms.
	SAMe	CT	Various mechanisms.
	Selenium	CT	Low dietary intakes of selenium have been linked with greater incidence of anxiety, depression and tiredness.
	Shatavari	IV	Thought to be mediated via serotonergic and noradrenergic systems and antioxidant activities.
	Tyrosine	CT	Precursor to neurotransmitters.
	Valerian	AS	
	Vitamin B_1 (thiamin)		Involved in neurotransmitter synthesis.
	Vitamin B_6 (pyridoxine)	TH	Supplementation can elevate GABA and serotonin levels by increasing production.
	Vitamin C	PH	Cofactor required for the biosynthesis of noradrenaline from dopamine and hydroxylation of tryptophan to serotonin; also a modulator of glutaminergic, cholinergic and GABAergic transmission.
	Withania	AS	Effects comparable to those of imipramine.
	Zinc	EP, CT	Inverse relationship between serum zinc and depression.
Antidiarrhoeal			
	Bilberry	TH, PH	Due to tannins and astringent activity.
	Colostrum	CT	Effective against some forms of infectious diarrhoea.
	Goldenseal	IV, AS, CT	Due to berberine constituent.
	Probiotics	CT	Includes infant, travellers', infectious, acute and antibiotic-induced diarrhoea.
	Psyllium	CT	
	Raspberry	TU, PH	Due to tannins and astringent activity.
	Sage	TU, PH	Due to tannins and astringent activity.
	Shatavari	AS	Similar to the drug loperamide.
	Thyme	TU, PH	Due to tannins and astringent activity.
Anti-emetic			
	Bacial skullcap	AS, CT	
	Ginger	AS, CT	Multiple mechanisms.
	Peppermint oil	CT	Peppermint oil inhalation.
	Shatavari	CT	Promotes gastric emptying.
Antifibrotic — See listing under Anticancer			
Antifungal — See listing under Antimicrobial			
Antihypertensive/hypotensive			
	Andrographis	AS	Involves adrenoceptors, autonomic ganglia receptors and a reduction in circulating angiotensin-converting enzyme. Constituent 14-deoxy-11, 12-didehydroandrographolide found to induce relaxation of vascular smooth muscle and decrease heart rate.
	Astragalus	AS	Intravenous administration in rats.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Baical skullcap	AS	Mechanism unknown; may be due to peripheral vasodilation, inhibition of lipoxygenase and reduced production and release of arachadonic acid.
	Calcium	CT	Results variable, possibly in 'salt sensitive' hypertension. Mechanisms speculated to include reduced cellular calcium influx, inhibition of vasoconstriction, reduced activity of renin-angiotensin system and improved Na/K.
	Chromium	AS	Effect on renin-angiotensin system.
	Coenzyme Q10	CT, CT	Mechanism unknown but may reduce total peripheral resistance.
	Evening primrose oil	CT	Effect may be mediated through prostaglandin metabolism.
	Fenugreek	IV	
	Fish oils	CT	Appears dose-dependent and DHA may have greater effect than EPA.
	Flaxseed oil	PH	Mechanisms unknown.
	Garlic	AS, CT	Renin–angiotensin and NO may be involved.
	Ginger	AS	Via stimulation of muscarinic receptors and blockade of calcium channels.
	Ginseng — Korean	IV, AS, CT	May be attributed to an angiotensin-converting-enzyme inhibitory effect.
	Green tea	AS, IV	Angiotensin-converting-enzyme inhibition.
	Hawthorn	TU, IV, AS	Mechanism unknown, but may reduce total peripheral resistance.
	Magnesium	CT	Affects NO release and vascular tone.
	Oats	CT	Mechanism unknown.
	Olive oil and Olive leaf	IV, AS	Mechanism unknown.
	Quercetin	AS, CT	Decreases blood pressure and restores endothelial function.
	Stinging nettle	AS	Administered IV; mechanism attributed in part to negative inotropic activity and vasodilatory effect.
	Vitamin C	CT	Results overall positive.
	Vitamin E	CT	Modulates vascular function, possibly via NO; may also normalise genetic endothelial dysfunction.
	Zinc	CT	Supplementation consistently reduced duration and volume of diarrhoea.
Anti-inflammatory			
	Adhatoda		Alkaloid fraction (deoxyvasicinone [22] naturally occurring quinazolinone alkaloid) shown to be equivalent to hydrocortisone in one study.
	Aloe	AS	Aloe vera gel reduces oxidation of arachidonic acid, thereby reducing prostaglandin synthesis and inflammation.
	Andrographis	IV	May involve promotion of ACTH and enhancement of adrenocortical function. Antioxidant mechanisms are likely to contribute to anti-inflammatory effect.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Baical skullcap	IV, AS	May bind a variety of chemokines and limit their biological function; inhibits COX-2, PGE_2, 5-lipoxygenase, suppresses iNOS protein expression and NO production.
	Bilberry	AS	Reduces oedema.
	Bitter melon	IV	Suppresses LPS-induced TNF alpha production.
	Black cohosh	AS	
	Brahmi	IV	Various mechanisms; inhibition of COX-2, 5-LOX and down-regulation of TNF-alpha; inhibition of PGE_2, histamine, serotonin and bradykinin release.
	Calendula	IV, AS	Reduces oedema
	Celery	AS	Mechanism unknown.
	Chamomile	AS	Most research uses topical application.
	Chondroitin	IV	Regulates gene expression and synthesis of NO and PGE_2; inhibition of NF-kB nuclear translocation; increases antioxidant enzymes.
	Chromium	AS	Reduces pro-inflammatory cytokines TNF-alpha, IL-6 and CRP.
	Cinnamon	IV, AS	
	Clove oil	AS	Due to the eugenol, beta-caryophyllene component, inhibits prostaglandin synthesis through COX-1 & -2 and inhibits leukotrienes release.
	Cocoa	PH	
	Damiana	AS	Mechanism unknown.
	Dandelion (root)	AS	Mild activity.
	Devil's claw	IV, AS, CT	Various mechanisms may be due in part to antioxidant activity. Constituent harpagoside shown to suppress COX-2 and iNOS.
	Dong quai	AS	
	Echinacea	IV, AS	Multiple constituents; multiple mechanisms including Inhibits COX-1 and COX-2.
	Elder	IV	Inhibited activation of nuclear factor kappaB and phosphatidylinositol 3-kinase.
	Eucalyptus	AS, CT	Inhibition of inflammatory markers such as TNF-alpha, COX enzymes, 5-lipoxygenase and other leukotrienes.
	Evening primrose oil	AS, CT	Precursor to PGE_1.
	Fenugreek	AS	Mechanism unknown.
	Feverfew	IV	Inhibition of COX enzymes, lipoxygenase, platelet-activating factor, cytokines and NO.
	Fish oils	AS, CT	Chiefly prostaglandin mediated.
	Flaxseed oil	AS	Attributed to metabolites of ALA in formation of anti-inflammatory eicosanoids and modulation of cytokine production.
	Garlic	IV, AS, CT	Mechanisms identified inhibiting TN-kappa, modification of COX activity and suppression of iNOS and NO.
	Gentian	IV	
	Ginger	IV, AS, CT	Various mechanisms.
	Ginkgo biloba	IV, AS	Demonstrated reduced PGE_2, TNF-alpha and NO production.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Ginseng — Korean	AS	Ginsenosides suppress NF-kappa-B and COX-2.
	Ginseng — Siberian	IV	Suppresses NO production and iNOS gene expression.
	Glucosamine	IV	Altering production of TNF-alpha, interleukins, prostaglandins, NO and cytokines.
	Goldenrod	AS	Mechanism unknown
	Goldenseal	IV, AS	Due to the berberine content.
	Grapeseed extract	IV, AS	Demonstrated inhibitory activity against COX-1 and -2, and 5-lipoxygenase.
	Green tea		
	Hawthorn	IV, AS	Chiefly due to the flavonoid constituents.
	Honey	CT	Topical use.
	Hops	IV, CT	Reduces NO and inhibits production of PGE_2.
	Horse chestnut	IV, AS	
	Lavender		
	Lemon balm	IV	Rosmarinic acid anti-inflammatory; eugenol inhibits COX-1 and -2.
	Licorice	PH, IV, AS	Largely mediated by cortisol, although other mechanisms likely to exist.
	Meadowsweet	TH	High salicylate content.
	Myrrh	AS	Activity exhibited in resin and oil.
	New Zealand green-lipped mussel	IV, AS, CT	Possibly via effects on prostaglandins and leukotrienes.
	Noni	IV, CT	Demonstrated reduced superoxide radicals and lipid peroxidases.
	Olive oil and Olive leaf	PH, CT	Inhibits platelet aggregation, lipoxygenase, eicosanoid production and modulates C-reactive protein.
	Perilla	IV, CT	Refined oil and seed extract modulates prostaglandin, leukotriene synthesis and inhibits 5-lipoxygenase.
	Probiotics	IV, CT	Multiple mechanisms specific to strains including down-regulation of proinflammatory cytokines.
	Pygeum	PH, IV	Modulation of prostaglandins, leukotrienes and other 5-lipoxygenase metabolites.
	Quercetin	IV, AS	Modulated neutrophil function, prostanoid synthesis, cytokine production and iNOS expression via inhibition of NF-Kappa-B pathway.
	Raspberry	TU, PH	Topically, due to tannins.
	Red yeast rice	CT	Various mechanisms; significant reduction of CRP.
	Rosemary	IV	Possibly via effects on prostaglandins and leukotrienes.
	St John's wort	IV, AS	Various mechanisms.
	St Mary's thistle	IV, AS	Various mechanisms.
	SAMe	IV, CT	Not prostaglandin mediated.
	Saw palmetto	IV	Dual inhibitor of the cyclo-oxygenase and 5-lipoxygenase pathways and decreases COX expression.
	Schisandra	IV	Demonstrated inhibition of NO production, prostaglandin E(2), COX-2, iNOS, nuclear factor-kappaB and leukotrienes in vitro.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Selenium	IV, AS	Possibly via effects on prostaglandins, cytokines and leukotrienes.
	Shark cartilage	AS	Multiple mechanisms including inhibition of IL-1 induced PGE (2) synthesis and down-regulation of vascular endothelial growth factor.
	Slippery elm	TU, TH	High mucilage content; soothes irritated and inflamed tissues.
	Stinging nettle	IV, EP, CT	Various mechanisms.
	Tea tree oil	AS	
	Thyme	IV	Constituent thymol.
	Turmeric	AS	Activities exerted through multiple mechanisms.
	Vitamin E		Inhibits phospholipase A2 activity, suppressing arachidonic acid metabolism.
	Wild yam	TU	
	Willowbark	CT	Chiefly due to salicylate content.
	Withania	IV, CT	Suppresses pro-inflammatory mediators in vitro and found to ESR in clinical trial.
Anti-lithic			
	Shatavari	AS	Reduced elevated urinary concentrations of calcium, oxalate and phosphate and increased urinary concentration of magnesium.
	Tribulus	IV, AS	Reduced urinary oxalate; in human studies activity attributed to diuretic action.
Antimicrobial			
	Albizia	IV, AS	Antifungal and antibacterial.
	Aloe vera	IV	Activity against *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, *Streptococcus pyogenes*, *Staphylococcus aureus*, *Escherichia coli, Shigella flexneri*, methicillin-resistant *Staphylococcus aureus, Enterobacter cloacae* and *Enterococcus bovis.*
	Andrographis	IV	Demonstrated significant antimicrobial and antifungal activity in vitro when compared to standard antibiotics.
	Baical skullcap	IV	Antibacterial, antiviral and antifungal. Antibacterial against peridontopathogens, *Salmonella typhimurium.*
	Bitter melon	IV	Antibacterial and antiviral — activity against *E. coli*, *Salmonella paratyphi*, *Shigella dysenterae* and *Streptomyces griseus*, *Helicobacter pylori*, *Mycobacterium tuberculosis.* Antiprotozoal activity against *Entamoeba histolytica.*
	Brahmi	IV	Significantly inhibited *H. pylori.*
	Calendula	IV	Antibacterial, antiviral and antifungal.
	Chamomile	IV	Bactericidal and fungicidal activities against Gram-positive bacteria (*Bacillus subtilis*, *Staphylococcus aureus*) and *Candida albicans*, *Escherichia coli*, *Streptococcus mutans.*
	Chitosan	AS	May exert antibacterial activity against *Bifidobacterium* and *Lactobacillus* spp; oral antibacterial activity against *Streptococcus mutans* and inhibits adhesion of *Candida albicans.* Exhibits antifungal activity.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Cinnamon	IV	Broad-spectrum antibacterial and antifungal activities. *Bacillus subtilis, Escherichia coli, Saccharomyes cerevisiae, Candida albicans*, *L. monocytogenes, Salmonella enterica* and *Helicobacter pylori;* antibiotic-resistant *E. coli* and *Staphylococcus aureus.*
	Clove oil	IV, AS	Demonstrated activity against Gram-negative anaerobic periodontal oral pathogens, including *Porphyromonas gingivalis*, *Prevotella intermedia*; also *Bacillus subtilis*, *Listeria monocytogenes*, *Salmonella enterica*, *Escherichia coli* and *Saccharomyces cerevisiae*; hepatitis C virus protease; human cytomegalovirus, herpes simplex virus 1; *Candida albicans, Helicobacter pylori and Staphlococcus epidermidis*.
	Cloves	IV	Antibacterial, antifungal and antiviral.
	Colostrum	IV	Hyperimmune colostrums exhibit widespread antimicrobial activity, including *Shigella flexneri, Escherichia coli, Clostridium difficile, Streptococcus mutans, Cryptosporidium parvum* and *Helicobacter pylori*.
	Cranberry	IV, AS, CT	Bacteriostatic — reduced adhesion of *Escherichia coli,* Gram-negative and Gram-positive bacteria to uroepithelial tissues, and of *Helicobacter pylori* to human gastrointestinal cells.
	Dunaliella salina	IV	Antibacterial.
	Echinacea	IV	Antiviral, antifungal and antiparasitic.
	Eucalyptus	IV, CT	Activity against *Pseudomonas aeruginosa*, *Bacillus subtilis*, *Enterococcus faecalis, Escherichia coli,* herpes simplex and oral pathogens.
	Garlic	IV, AS, CT	Antibacterial, antifungal, antiviral and antiparasitic. Inhibits *Salmonella typhi, Vibrio cholerae, Tricophyton violaceum, Trichomonas vaginalis*, *Helicobacter pylori* and herpes simplex.
	Gentian	IV	Inhibited *Helicobacter pylori*.
	Ginger	IV, AS	Antibacterial, antiviral and antifungal.
	Goldenrod	IV	Antibacterial activity against species of *Bacillus, Proteus* and *Staphylococcus*.
	Goldenseal	IV	Demonstrated for the whole extract and berberine constituent against *Staphylococcus aureus*, *Streptococcus sanguis*, *E. coli*, *Pseudomonas aeruginosa.* Methanolic extract of rhizome inhibited *H. pylori* in vitro. Also demonstrated for berberine, activity against *Shigella dysenteriae*, *Bacillus subtilis*.
	Grapeseed extract	IV	Antibacterial and antifungal action.
	Green tea	IV, AS	Active against certain strains of *Staphylococcus* spp, *Streptococcus* spp, *Escherichia coli*, *Salmonella* spp; also *Corynebacterium suis*, *Helicobacter pylori*, *Porphyromonas gingivalis* and *Prevotella* spp, *Streptococcus mutans, S. salicarius and Helicobacter pylori*. Green tea is more active than black.
	Guarana	IV	Active against *Escherichia coli*, *Salmonella typhimurium*, *Staphylococcus aureus* and *Streptococcus mutans*.
	Gymnema sylvestre	IV	Active against *Bacillus pumilus*, *B. subtilis*, *Pseudomonas aeruginosa*, *Staphylococcus aureus, Klebsiella pneumoniae, P. aeruginosa, Escherichia coli* and *Salmonella typhi*.
	Hawthorn	IV	Antibacterial activity against Gram-positive *Micrococcus flavus, Bacillus subtilis* and *Lysteria monocytogenes*.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Honey	IV, CT	Leptospermum (manuka) honey can inhibit the growth of several important bacterial pathogens, including *Escherichia coli*, *Salmonella typhimurium*, *Shigella sonnei*, *Listeria monocytogenes*, *Staphylococcus aureus*, *Bacillus cereus* and *Streptococcus mutans*. Also useful against certain strains of methicillin-resistant *Staphylococcus aureus* and vancomycin-sensitive and resistant enterococci. Topical use.
	Hops	IV	Activity against the Gram-positive bacteria *Bacillus subtilis* and *Staphylococcus aureus* A, but almost no activity against the Gram-negative bacterium *Escherichia coli*.
	Horseradish	IV	Gram-negative and Gram-positive bacteria.
	Lavender oil	IV	Antibacterial, antifungal and mitocidal. Activity against *Staphylococcus aureus* and vancomycin-resistant enterococcus.
	Lemon balm	IV	Eugenol has antibacterial activity against *Escherichia coli* and *Staphylococcus aureus*.
	Licorice	IV, AS	Against Gram-positive and Gram-negative bacteria.
	Meadowsweet	IV	Bacteriostatic activity has been reported against *Staphylococcus aureus*, *S. epidermidis*, *Escherichia coli*, *Proteus vulgaris* and *Pseudomonas aeruginosa*.
	Mullein	IV	Antiviral and antibacterial.
	Myrrh	IV, CT	Activity against *Escherichia coli*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*.
	Noni	IV	Activity against *Escherichia coli, Mycobacterium tuberculosis* and *Ascaris lumbricoides*.
	Olive	IV	Activity against viruses, bacteria, yeasts and fungi. Activity against 8 strains of *H. pylori*.
	Orange	IV	Tuberculosis; against *Escherichia coli* and *Staphylococcus aureus*.
	Pelargonium	IV	Activity against *Staphylococcus aureus*, *Streptococcus pneumoniae, Haemophilus influenzae, Moraxella catarrhalais, Micobacterium tuberculosis.*
	Peppermint	IV	Peppermint oil is active against *Helicobacter pylori*, *Staphylococcus aureus*, *Escherichia coli*, *Salmonella enteritidis*, *Listeria monocytogenes*, *Shigella sonnei* and *Micrococcus flavus,* and a variety of fungi.
	Perilla	IV	Activity against oral streptococci and *Porphyromonas gingivalis*.
	Prebiotics	AS	Through stimulation of beneficial bacteria growth, subsequent excretion of antimicrobial compounds inhibiting colonisation of pathogenic bacteria.
	Probiotics	IV	Specific strains of probiotics inhibit or kill *Helicobacter pylori*.
	Rhodiola	IV	Against *Staphylococcus aureus*.
	Rosemary	IV	Activity against a variety of bacteria and fungi.
	Sage	IV	Active against *Staphylococcus aureus*, *Escherichia coli*, *Salmonella* spp, *Shigella sonnei*, *Klebsiella ozanae*, *Bacillus subtilis* and various fungi, including *Candida albicans*. Antimicrobial activity also reported for sage oil.
	St John's wort	IV	Active against MRSA and other Gram-positive bacteria.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Shark cartilage	IV	Activity against protozoa, fungi and both Gram-positive and Gram-negative bacteria.
	Shatavari	IV	Activity against *Escherichia coli*, *Shigella sonnei*, *S. dysenteriae, S. flexneri, Vibrio cholerae, Salmonella typhi, Bacillus subtilis* and *Staphylococcus aureus*.
	Tea tree oil	IV, CT	Activity against *Corynebacterium* spp, *Klebsiella pneumoniae*, *Micrococcus luteus*, *Micrococcus varians*, *Micrococcus* spp, *Pseudomonas aeruginosa*, *Acinetobacter baumannii*, *Serratia marcescens*, *Staphylococcus aureus*, *S. capitis*, *S. epidermidis*, *S. haemolyticus*, *S. hominis*, *S. saprophyticus*, *S. warneri*, and *S. xylosus*. Successful trials in acne, methicillin-resistant *Staphylococcus aureus.* Topical use.
	Thyme	IV	Activity against *Escherichia coli*, *Listeria monocytogenes*, *Streptococcus mutans* and *Salmonella enterica*, *Helicobacter pylori, Klebsiella pneumoniae, Haemophilus influenzae* and *Candida albicans*.
	Tribulus	IV	Gram-negative and Gram-positive bacteria.
	Withania	IV, AS	Activity against *Staphylococcus aureus*, *Listeria monocytogenes*, *Bacillus anthracis*, *B. subtilis*, *Salmonella enteridis S. typhimurium* and *Escherichia coli*.
Antifungal			
	Baical skullcap	IV	Antifungal activity against *Candida albicans, Cryptococcus neoformans* and *Pityrosporum ovale.*
	Calendula	IV	Activity against *Aspergillus niger*, *Rhizopus japonicum*, *Candida albicans*, *Candida tropicalis* and *Rhodotorula glutinis*.
	Cinnamon	IV	
	Chitosan	AS	
	Clove oil	IV	Observed activity against species belonging to *Eurotium, Aspergilis* and *Penicillium* genera in vitro.
	Echinacea	IV	Activity observed against *Saccharomyces cerevisiae*, *Candida shehata*, *C. kefyr*, *C. albicans*, *C. steatulytica* and *C. tropicalis*.
	Ginger	IV	Ginger oils have shown activity against yeasts and filamentous fungi in vitro.
	Globe artichoke	IV	Antifungal activity.
	Goldenrod	IV	Inhibitory effects on *Candida* and *Cryptococcus* spp have been demonstrated for triterpenoid glycosides.
	Goldenseal	PH	Berberine constituent inhibits *Candida* spp.
	Honey	IV	Activity against *Candida albicans, C. glabrata* and *C. dubliniensis*.
	Hops	IV	Activity against the fungus *Trichophyton mentagrophytes* var. *interdigitale*, but almost no activity against the yeast *Candida albicans*.
	Lavender oil	IV	Activity against *Aspergillus nidulans* and *Trichophyton megatrophyles*.
	Orange essential oil		Effective against resistant fungal skin infections.
	Peppermint	IV	Fungistatic and fungicidal activity against *Trichophyton* and *Candida albicans*.
	Myrrh	IV	Activity against *Candida albicans*.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Rosemary	IV	
	Sage	IV	
	Tea tree oil	IV, CT	*Candida*, toenail onychomycosis.
	Thyme	IV	*Saccharomyces cerevisiae* and *Candida albicans*.
	Tribulus	IV	Strongest activity found to be against *Candida albicans*.
	Turmeric	IV, AS	Antifungal and antiprotozoan activity.
	Withania	IV	*Withanolides coagulens*, *Allescheria boydii*, *Aspergillus niger*, *A. flavus, Curvularia lunata*, *Drechslera rostrata*, *Epidermophyton floccosum*, *Fusarium oxysporum, F. verticilloides, Microsporum canis*, *Nigrospora oryzae*, *Pleurotus ostreatus* and *Stachybotrys atra*.
Antiviral			
	Aloe vera	IV, CT	Virucidal against herpes simplex 1 and 2, vaccinia virus, parainfluenza virus and vesicular stomatitis virus.
	Andrographis	IV	Andrographolides antiviral activity against HSV1 in vitro.
	Baical skullcap	IV, AS	
	Bitter melon	IV	Against EBV, HSV 1 & 2, coxsackievirus B3 and polio viruses.
	Calendula	IV	Virucidal activity against influenza viruses and suppresses the growth of herpes simplex virus.
	Chamomile	IV	Inhibitory activity against HIV activation; inhibits herpes virus in vitro.
	Cranberry	IV	Non-specific antiviral.
	Echinacea	IV	Activity against herpes simplex virus.
	Elder	IV	Effective against 10 strains of influenza.
	Ginger	IV	Antirhinoviral activity.
	Ginseng — Siberian	IV	Inhibits the replication of RNA-type viruses such as human rhinovirus, respiratory syncytial virus and influenza A virus.
	Glucosamine	IV	Antiviral activity.
	Green tea	IV	Interferes with virus absorption; antiviral activity has been identified against HIV, herpes simplex 1, influenza A and B, rotavirus and enterovirus, Epstein-Barr virus.
	Gymnema sylvestre		Antiviral activity.
	Hawthorn	IV	Herpes simplex 1.
	Hops	IV	Herpes simplex 1 and 2, cytomegalovirus and anti-HIV activity.
	Horseradish	IV	Activity against transmission of avian influenza.
	Lemon balm	IV, AS, CT	Herpes simplex 1 and 2, HIV.
	Licorice	IV, AS	Activity against SARS-CV, HIV, influenza A, Ebola virus, herpes simplex virus 1, Epstein-Barr virus, hepatitis B and C, encephalitis, respiratory syncytial virus, arboviruses, vaccinia virus and vesicular stomatitis virus.
	L-Lysine	IV, CT	Clinical trials show inconsistent results against herpes simplex virus.
	Mullein	IV	Antiviral activity against several influenza A and B strains, HSV.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Olive	IV	Antiviral activity against HIV.
	Orange		Potent inhibitory activity on rotavirus infection.
	Peppermint	IV	Antiviral activity demonstrated against HSV-1 and -2.
	Quercetin	IV, AS	Dose-dependent reduction in the infectivity and intracellular replication of HSV-1, polio virus type 1, para influenza virus type 3 and respiratory syncytial virus.
	Rosemary	IV	Antiviral activity against HSV and HIV-1.
	St John's wort	IV, AS	Antiretroviral activity appears to be photo-activated.
	Sage	IV	
	Stinging nettle	IV	Activity against HIV-1, HIV-2, human cytomegalovirus, respiratory syncytial virus and influenza A.
	Tea tree oil	IV	Activity against herpes simplex 1 and 2.
	Thyme oil	IV	Demonstrates antiviral activity against HSV-1 and -2 and acyclovir-resistant strain of the virus.
Antimalarial			
	Andrographis	IV, AS	Demonstrated antimalarial effects. Four xanthones isolated from *A. paniculata* demonstrated antimalarial effects against *Plasmodium berghei*.
	Green tea	IV	Strongly inhibits growth of *Plasmodium falciparum*.
	Turmeric	IV	Inhibition of growth of cloroquine-resistant *Plasmodium falciparum*.
Antiparasitic			
	Goldenseal	PH	Berberine inhibits *Entamoeba histolytica*, *Giardia lamblia*, *Trichomonas vaginalis*.
	Myrrh	CT	Effective against schistosomiasis, fascioliasis.
	Peppermint	IV, AS	Against nematodes and antigiardial activity.
Antimigraine (i.e. reducing frequency and/or severity of attacks)			
	Coenzyme Q10	CT	Mechanism unknown — possibly via mitochondrial stabilisation.
	Feverfew	CT, AS	Reduced frequency and severity of migraine headaches. Reduces serotonin release from platelets; possibly other mechanisms.
	Magnesium	CT	Mechanism unknown; does exert effect upon serotonin receptors, NO synthesis and release and neurotransmitters.
	SAMe	CT	Reduced pain reported.
	Vitamin B_2 (riboflavin)	CT	Reduced frequency and duration of migraines with large doses.
Antioxidant			
	Adhatoda	IV	Induces glutathione S-transferase and DT-diaphorase in lungs and forestomach, and superoxide dismutase and catalase in kidneys.
	Andrographis	AS	Increases liver superoxide dismutase, glutathione peroxidase, glutathione reductase and catalase concentrations, thereby increasing endogenous antioxidant production by the liver.
	Astragalus	AS	Raises superoxide dismutase activity in the brain and liver.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Baical skullcap	IV, AS	Baicalin antioxidant effect based on scavenging superoxide radicals; baicalein xanthine oxidase inhibitor.
	Beta-carotene	CT	Quenches singlet oxygen, scavenges peroxyl radicals and inhibits lipid peroxidation.
	Bilberry	PH, AS	Contains anthocyanosides shown to exhibit superoxide radical scavenging and cytoprotective activity.
	Brahmi	IV, AS	Direct free-radical-scavenging activity and increases endogenous antioxidant systems.
	Calendula	IV	Reduces levels of superoxide and hydroxyl radicals, suggesting a free-radical-scavenging effect; reduces lipid peroxidation.
	L-Carnitine	IV	Inhibits lipid peroxidation; may have an effect on superoxide-anion-radical scavenging and hydrogen-peroxide scavenging.
	Celery	AS	
	Chamomile	IV	Inhibits lipid peroxidation.
	Chondroitin	AS	Increases antioxidant enzymes and enhances antioxidant activity.
	Chromium	AS, CT	
	Cinnamon	IV	
	Clove oil	PH, IV	Antioxidant research focuses on constituent eugenol.
	Cocoa	IV, AS, CT	Activities attributed to high phenolics and flavonoids; reduces lipid oxidation.
	Coenzyme Q10		Buffers free radicals produced during oxidative phosphorylation and inhibits the mitochondrial permeability pore.
	Colostrum	AS	Increases superoxidase dismutase and glutathione peroxidase, and reduces oxidative stress and NO overproduction.
	Cranberry	IV	Polyphenolic compounds exert substantial antioxidant capacity. The antioxidant activity of flavonol glycosides are comparable or superior to that of vitamin E; increases excretion of oxalic and uric acid.
	Creatine	AS	
	Dandelion	AS	
	Dunaliella salina	AS	
	Echinacea	IV	Activity attributed to numerous antioxidant constituents found in echinacea, such as vitamin C, beta-carotene, flavonoids, selenium and zinc.
	Elder	IV	Activity attributed to flavonoid constituents quercertin, isoquercertin and rutin.
	Fenugreek	IV	
	Garlic	PH, IV	Capable of directly scavenging free radicals, and indirect activity by enhancing endogenous antioxidant systems such as glutathione, superoxide dismutase, catalase and glutathione peroxidase.
	Gentian	IV	
	Ginger	AS	Significantly lowers free-radical levels and raises endogenous antioxidant levels; protects against lipid peroxidation; modulates prostaglandin synthesis.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Ginkgo biloba	IV, AS	The extract and several of its individual constituents (quercetin, kaempferol) have demonstrated significant antioxidant properties; used topically, increases the activity of superoxide dismutase within skin.
	Ginseng — Korean	IV, AS	Suppresses lipid peroxidation.
	Globe artichoke	IV, CT	Increases plasma total antioxidant capacity.
	Glutamine		Precursor to glutathione.
	Goji	AS, CT	Stimulates endogenous antioxidant mechanisms; increases superoxide dismutase, glutathione peroxidase and reduces lipid peroxidation.
	Grapeseed extract	IV, AS	Significantly greater effects than vitamins C and E and beta-carotene; procyanidins prevent vitamin E loss and regenerate alpha-tocopherol radicals back to their antioxidant form.
	Green tea	IV, AS, CT	Inhibits lipid peroxidation; scavenges hydroxyl and superoxide radicals.
	Hawthorn	IV, AS	Direct and indirect activities.
	Honey	IV	Attributed to flavonoid content.
	Horse chestnut	IV	Dose dependently inhibits enzymatic and non-enzymatic lipid peroxidation in vitro.
	Lavender	IV	
	Lemon balm		
	Licorice	IV, CT	Reduces lipid peroxidation.
	Lutein and zeaxanthin	IV, AS	Increased glutathione levels and decreased retinal apoptosis.
	Lycopene	IV	Particularly against singlet oxygen and free radicals.
	Meadowsweet	IV	
	Mullein	IV	
	Noni	IV, CT	Inhibits COX-1 and -2 in vitro.
	Oats	CT	Avenanthramides increase antioxidant capacity.
	Olive leaf and olive oil	IV, CT	Attributed to phenolic compounds.
	Orange	IV	Inhibits lipid peroxidation.
	Peppermint	IV	Antioxidant and free-radical-scavenging activity.
	Perilla	IV	Multiple constituents identified exhibit antioxidant capacity.
	Policosanol	IV	Reduces oxidation of LDL-cholesterol.
	Quercetin	CT	
	Raspberry		Attributed to high tannin content.
	Red clover	PH	Isoflavones display antioxidant activity.
	Rhodiola	AS, CT	Increases endogenous antioxidant production.
	Rosemary	IV, AS	Chiefly due to carnosol and carnosic acid.
	Sage	AS	Chiefly due to labiatic acid and carnosic acid.
	St Mary's thistle	IV, AS	Antioxidant and free-radical-scavenging activity.
	SAMe	IV	Exhibited direct antioxidant activity in vitro.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Schisandra	IV	Direct activity and increases glutathione levels.
	Selenium		Essential component of glutathione peroxidase and thioredoxin reductase.
	Shark cartilage	IV	
	Shatavari	PH, IV, AS	Inhibition of lipid peroxidation and increase in antioxidant enzyme systems.
	Slippery elm	IV	Free-radical-scavenging activity may relate to anti-inflammatory action.
	Soy	IV, CT	Demonstrated in vitro; however clinical results inconclusive.
	Stinging nettle	IV, AS	Shown to scavenge free radicals, hydrogen peroxide and superoxide anion radicals; also regulates glutathione reductase, glutathione peroxidase and superoxide dismutase in vivo.
	Taurine		
	Thyme	IV	Exhibits potent antioxidant effects.
	Turmeric	IV, AS	Multiple mechanisms of action.
	Tyrosine	IV	Free-radical, superoxide-anion-radical and hydrogen-peroxide scavenging.
	Vitamin A		Free-radical-scavenging properties.
	Vitamin B_2 (riboflavin)		By itself, but also as part of the enzyme glutathione reductase.
	Vitamin B_3	IV	
	Vitamin B_5	IV	Indirect antioxidant action.
	Vitamin B_6	IV	Displayed antioxidant action in vitro and in vivo.
	Vitamin C	IV	Scavenges free-radical oxygen species and non-radical reactive species.
	Vitamin E	IV, AS, CT	Considered to be the most important and potent lipid-soluble antioxidant. It prevents free radical damage to polyunsaturated fatty acids within the phospholipid layer of each cell membrane and oxidation of LDL-cholesterol.
	Wild yam	PH	
	Withania	IV, AS	Most likely by increasing activity of endogenous antioxidant enzymes.
	Zinc		Indirect and direct activities.
Antiparasitic — See listing under Antimicrobial			
Antiplatelet — See listing under Blood thinning			
Antipruritic			
	Chamomile	AS	
	Chickweed	TU	Topical use; effect due to saponins.
	Oats	CT	Topical use.
Antipyretic			
	Andrographis	IV, AS, CT	
	Fenugreek	AS	
	Willowbark	PH	Effect chiefly due to salicylate content.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
Antispasmodic			
	Adhatoda	AS	Essential oil.
	Brahmi	AS	Acts on smooth muscle; effect due to inhibition of calcium influx into the cell.
	Calendula	IV	Effect due to calcium-channel-blocking and cholinergic activity.
	Chamomile	IV	Dose dependent.
	Cinnamon	AS	Active constituent is cinnameldehyde.
	Clove oil	PH	Effect due to the eugenol, beta-caryophyllene component.
	Feverfew	IV	Decreases vascular smooth muscle spasm.
	Globe artichoke	IV	
	Goldenrod	AS	
	Hops	TU	
	Horseradish		
	Kava kava	IV, AS	Acts on skeletal muscles.
	Magnesium		
	Myrrh	EV	Due to T-cadinol, and several minor components.
	Peppermint	IV, CT	Multiple mechanisms identified.
	Rosemary	TU	Used for mild cramp-like gastrointestinal and biliary upsets, as well as for tension headache, renal colic and dysmenorrhoea.
	Sage	AS	
	St John's wort	AS	Most likely mediated via GABA activity.
	Saw palmetto	IV	
	Thyme	IV	
	Tribulus	IV, PH	Dose-dependent decrease in peristaltic movements.
	Turmeric	AS	Smooth muscle relaxant, possibly through calcium-channel blockade.
	Valerian	IV, AS	Acts on smooth muscle.
	Wild yam	TU	
Antithrombotic — See listing under Blood thinning			
Antitussive			
	Adhatoda	AS	Comparable to codeine when cough is due to irritant stimuli.
	Chickweed	TU	Saponins irritate mucous membranes.
	Cocoa	AS	Antitussive effect may be mediated peripherally through an inhibitory affect on afferent nerve activation.
	Eucalyptus	AS, CT	Various mechanisms.
	Licorice	AS	Mediated by liquiritin apioside.
	Passionflower	AS	
	Shatavari	AS	Dose-dependent cough inhibition.
	Thyme	AS	

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
Anti-ulcer/anti-ulcerogenic (i.e. prevention and/or treatment)			
	Brahmi	AS	Fresh juice of whole plant enhanced mucin secretion and mucosal glycoprotein and decreased cell shedding.
	Chamomile	AS	Prevented formation of ulcers and reduced healing time.
	Fenugreek	IV, AS	Soluble gel fraction formed by polysaccharide and/or flavonoid components.
	Ginger	AS	
	Ginseng — Korean	AS	Mechanism attributed to inhibition of acid secretion, increased mucin secretion and antioxidant properties.
	Lemon balm	AS	Activity associated with reduced acid output and increased mucin secretion, an increase in prostaglandin E_2 release and a decrease in leukotrienes.
	Licorice	CT	Ability to promote mucosal repair and reduce symptoms of active ulcer.
	Meadowsweet	IV, AS	Protective effects against stomach ulcers induced by acetylsalicylic acid; however, no protection was seen against ulcers produced under high-acid environments or due to stimulation by histamine. Effect may be prostaglandin-mediated.
	St Mary's thistle	AS	Associated with reduced acid output, increased mucin secretion, increased prostaglandin E_2 release and decreased leukotriene release.
	Shatavari	AS	Inhibition of hydrochloric acid and protection of gastric mucosa.
	Turmeric	CT	May reduce symptoms.
Antiviral — See listing under Antimicrobial			
Anxiolytic — See listing under Anti-anxiety			
Astringent			
	Bilberry	PH	Attributed to significant tannic content.
Blood thinning			
Anticoagulant			
	Dong quai	CT	Ferulic acid found to inhibit platelet aggregation.
	Evening primrose oil	TH	PGE_1 production results in a cascade of reactions that ultimately inhibit platelet aggregation and cause vasodilation.
	Ginkgo biloba	CT	
	Meadowsweet	IV, AS	
	Ginseng — Siberian	CT, AS	Decreases blood coagulation normally induced by intensive training of athletes.
	Turmeric	IV, AS	Demonstrated for curcumin.
Antiplatelet			
	Andrographis	IV, AS, CT	Andrographolide, AP3 and four flavonoids inhibit thrombin and PAF-induced platelet aggregation. Andrographolide and AP3 inhibit extracellular signal-regulated kinase 1/2 pathway in vitro.
	Baical skullcap	IV	
	Clove oil	IV	Due to the eugenol component.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Cocoa	IV, CT	Due to polyphenol content.
	Dong quai	CT	Ferulic acid found to inhibit platelet aggregation.
	Evening primrose oil	TH	PGE_1 production results in a cascade of reactions that ultimately inhibit platelet aggregation and cause vasodilation.
	Feverfew	IV, AS, CT	No significant effects were seen in a clinical study of 10 patients receiving feverfew.
	Fish oils	AS, CT	Enhance anti-aggregatory and anti-adhesive platelet activity and reduce several coagulation factors.
	Flaxseed	PH	
	Garlic	IV, CT	Multiple mechanisms.
	Ginger	CT	Gingerols inhibit platelet activation.
	Ginkgo biloba	CT	Platelet-activating-factor antagonist.
	Ginseng — Korean	IV, AS	Ginsenosides inhibit platelet aggregation.
	Ginseng — Siberian	IV	3,4-dihydroxybenzoic acid constituent.
	Grapeseed extract	IV	Combination of grapeseed and grape skin produces a greater effect.
	Green tea		
	Guarana	IV, AS	Decreases thromboxane synthesis.
	Licorice	IV, AS	Isoliquiritigenin inhibits platelet aggregation in vitro and in vivo.
	Myrrh	CT	Gum guggul fraction.
	Policosanol	AS, CT	Inhibits platelet aggregation.
	Rosemary	IV, AS	
	Schisandra	IV	Several lignans inhibit platelet-activating factor.
	Turmeric	IV, AS	Demonstrated for curcumin.
	Vitamin E	IV	Demonstrated in vitro, but in vivo tests have been inconsistent; likely only at very high doses.
	Willowbark	CT	
Antithrombotic			
	Andrographis	AS, CT	Inhibits production of thromboxane A2 and stimulates PGE_2.
	Baical skullcap	IV	Baicalein inhibited the elevation of calcium induced by thrombin and thrombin receptor agonist peptide.
	Evening primrose oil	TH	PGE_1 production results in a cascade of reactions that ultimately inhibit platelet aggregation and cause vasodilation.
	Fish oils	AS, CT	Inhibits thromboxane A2 and coagulation factors.
	Flaxseed	PH	Inhibition of AA, resulting in EPA replacing it on cell membrane, decreases thromboxane synthesis.
	Garlic	IV, CT	Inhibits thromboxane A2 formation.
	Ginseng — Siberian	AS	Protects against immobilisation-induced thrombosis.
	Guarana	IV, AS	Decreases thromboxane synthesis.
	Licorice	IV, AS	Effective thrombin inhibitor in vivo.
	Policosanol	CT	Inhibits thromboxane.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Rosemary	IV, AS	Demonstrated in vitro and in vivo.
Bone density protection			
	Calcium	CT	Assists with calcium deficiency, BMD and osteoporosis prophylaxis.
	Chromium	CT	Modulative of insulin, reduced bone resorption and promotion of collagen by osteoblasts.
	Evening primrose oil	AS	Increases intestinal calcium absorption and balance.
	Hops	CT	Exerts oestrogen-like activities on bone metabolism.
	Licorice	IV	Constituent glabridin may enhance osteoblast function.
	L-Lysine	CT	Increases intestinal calcium absorption.
	Magnesium	CT	
	Quercetin	IV, AS	Prevents bone loss by affecting osteoclastogenesis.
	Red clover	PH, AS, CT	
	Red yeast rice	IV, CT	Strong bone anabolic effects in vitro and in vivo attributed to naturally occurring flavonoids and statins.
	Schisandra	PH	Lignans stimulated proliferation and activity of alkaline phosphatase in osteoblasts.
	Soy	IV, CT	Stimulates the synthesis and expression of alkaline phosphatase in osteoblasts. May be more effective in perimenopausal subjects.
	Vitamin C	EP, CT	
	Vitamin D	CT	Mediated through maintaining calcium and phosphorus homeostasis and osteocalcin expression, PTH; oestrogen biosynthesis and cell growth regulation.
Capillary stabilisation			
	Bilberry	AS	Stabilises membrane phospholipids; increases the synthesis of mucopolysaccharides of the connective ground substance and restores altered mucopolysaccharidic pericapillary sheath; improves ischaemic damage and preserves capillary perfusion; inhibits increased permeability of reperfusion and saves arteriolar tone.
	Ginkgo biloba	AS	Due to proanthocyanidin content.
	Grapeseed extract	AS, CT	Cross-links collagen fibres, reducing capillary permeability.
	Hawthorn		Flavonoid content improves vascular repair.
	Horse chestnut	IV, AS	Multiple mechanisms.
	Vitamin C		Essential for the formation of collagen.
Cardioprotective			
	Arginine		Formation of NO.
	Beta-carotene	AS	Antioxidant mechanisms.
	Cocoa	EP	Polyphenol content responsible for protective effects.
	Coenzyme Q10	AS, CT	Various mechanisms, including antioxidant activity.
	Dong quai	IV, AS	Prolonging of cardiac refractory period and correcting atrial fibrillation.
	Fish oils	CT	Various mechanisms.
	Flaxseed oil	CT	Various mechanisms associated with ALA.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Folate		Reducing Hcy.
	Ginkgo biloba	CT	Promotes vasodilation and increased blood flow through arteries, veins and capillaries.
	Ginseng — Korean	IV, AS	Diverse mechanisms including antioxidant, vasomotor functioning, reduced platelet adhesion, ion channels and altered neurotransmitter release.
	Ginseng — Siberian	AS	Activity due to increased endogenous opioid peptide levels.
	Grapeseed extract	IV, AS	Various mechanisms.
	Glutamine	IV	Maintains myocardial glutamate, ATP and phosphocreatine and prevents lactate accumulation in vitro.
	Hawthorn	AS, CT	Multiple mechanisms demonstrated in vitro and in vivo.
	Lycopene	EP	
	Magnesium	AS, CT	Multiple mechanisms.
	Olive	CT	Multifaceted: reduced lipidoxidation, reduced LDL oxidation; reduces oxidative damage, inflammation, blood pressure; anti-atherogenic and anti-thrombotic.
	Quercetin	IV, AS	Vasorelaxant, anti-inflammatory and antioxidant.
	Rhodiola	AS	
	St Mary's thistle	IV	Partly due to antioxidant effects.
	Schisandra	AS	Activity seen for schisandrin B constituent.
	Selenium	CT	
	Shatavari	AS	
	Soy	ES, CT	Decreased LDL and triglycerides and increased HDL.
	Tribulus	AS, CT	Possible due to inhibition of ACE activity.
	Vitamin C	EP	
	Vitamin E	IV, CT	Regulates vascular smooth muscle cell proliferation; anti-inflammatory, antioxidant and antiplatelet.
	Withania	PH, IV, AS	Most likely due to restoration of myocardial oxidant-antioxidant balance and marked anti-apoptotic properties.
Chemoprotection — See listing under Anticancer			
Choleretic (i.e. increased bile production and flow)			
	Andrographis	AS	Dose-dependent increase in bile flow and bile salt and acid production.
	Chamomile	AS	Chamomile increases bile production.
	Dandelion (root)	TU	
	Devil's claw	TU	Increased bile production.
	Ginger	AS	
	Globe artichoke	AS, CT	Increased bile secretion.
	Peppermint	AS, CT	Exerts relaxing effect on gall bladder and small intestine.
	St Mary's thistle	AS	Impact on bile secretion.
Chologogue (i.e. increased bile flow)			
	Celery	AS	Increases bile acid secretion.
	Globe artichoke	AS	Increased bile flow.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Turmeric	IV, AS	Stimulates contraction of the gall bladder and promotes the flow of bile.
	Wild yam	AS	
Chondroprotective			
	Chondroitin	IV, AS, CT	Various mechanisms.
	Devil's claw	IV, AS	The tissue inhibitor of metalloproteinase-2 is involved.
	Glucosamine	IV, CT	Proteoglycan biosynthesis and production of hyaluronic acid; increases APL activity, collagen synthesis, osteocalcin secretion and mineralisation in osteoblastic cells.
	SAMe	IV, AS	
	Vitamin B_3	CT	Via suppression of cytokine-mediated induction of NO synthase.
	Withania	IV, AS	
CNS sedative			
	Chamomile	AS, CT	Demonstrating a benzodiazepine-like activity.
	Hops	TU, CT, AS	Through activation of melatonin receptors.
	Lavender oil	AS, CT	Inconsistent results.
	Lemon balm	CT	High doses.
	Kava kava	IV, AS	
	Passionflower	AS	Mechanism unknown.
	Peppermint	AS	
	Valerian	IV, AS, CT	
CNS stimulant			
	Guarana	CT	Possibly due to caffeine content.
	Peppermint	AS	Possibly due to menthone, mediated by dopamine.
Cognitive enhancement/activator			
	Albizia	AS	Effects due to saponins.
	Astragalus	AS	In combination with other herbs.
	Brahmi	AS, CT	Possible mechanisms of action are antioxidant and anticholinesterase activity.
	Ginkgo biloba	IV, AS, CT	Cholinergic activity.
	Ginseng — Korean	CT	Enhances survival of newly formed neurons.
	Guarana	AS, CT	
	Lemon balm	CT	Dose dependent, cholinergic.
	Licorice	AS	May be due to cholinergic effects.
	Quercetin	AS	
	Rhodiola	AS, CT	Promotes release of monoamine neurotransmitters.
	Rosemary	CT	
	St John's wort	CT	Cholinergic effects.
	Soy	PH, CT	May mimic the action and functions of oestrogen in the brain.
	Tyrosine	CT	
	Vitamin B_6		Possibly due to reduction of homocysteine.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Withania	IV, AS	Potent acetylcholinesterase inhibitory activity exhibited in vitro.
Diuretic			
	Celery	TU	
	Dandelion (leaf)	TU	Considered a potassium-sparing diuretic.
	Elder	TU, IV	Study found elder exhibited diuretic properties comparable to hydrochlorothiazide.
	Globe artichoke	AS	
	Goldenrod	AS	Excretion of calcium can increase whereas excretion of potassium and sodium decreases.
	Green tea	PH	Chiefly due to caffeine content.
	Guarana	PH	Chiefly due to caffeine content.
	Horseradish	TU	
	Stinging nettle leaf	AS	
	Tribulus	AS	With high doses.
Expectorant			
	Chickweed	TU	Saponins irritate mucous membranes.
	Licorice	TU, TH	Stimulates tracheal mucus secretion, facilitating elimination of mucus from the respiratory tract.
	Mullein	PH	Due to saponins.
	Thyme	AS	Due to saponins.
Ergogenic effects			
	Rhodiola	AS, CT	Results conflicting.
Gastrointestinal effects			
	Astragalus	AS	Improves gastrointestinal motility; strengthens the movement and muscle tone of the small intestine.
	Bilberry	IV	Specific anthocyanin-increased efficiency of gastric mucosal barrier.
	Cinnamon	AS	
	Colostrum	IV, AS, CT	Improves gut permeability and reduces NSAID-induced damage.
	Dong quai	AS	Through promotion of growth factors, antioxidant activity and anti-inflammatory effects.
	Fenugreek	AS	Enhances pancreatic lipase activity, intestinal lipase activity and the disaccharides sucrase and maltase.
	Gentian	TU, CT	Stimulates the flow of saliva, gastric juice and bile secretion.
	Ginger	AS, CT	Stimulates the flow of saliva, bile and gastric secretions; anti-ulcer activity.
	Ginseng — Korean	IV	Carminative action.
	Glucosamine	PH	Glycoproteins protect bowel mucosa.
	Glutamine	IV, AS	Aids in the proliferation and repair of intestinal cells.
	Guarana	CT	Increases gastric acid secretion and delays gastric emptying time in combination with yerbe mate and damiana.
	Hawthorn		Dose-dependent gastroprotective activity.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Horseradish		Oil may exert a gastric irritant effect.
	Lavender	TU	Carminative action.
	Licorice	AS	Increases mucosal blood flow and mucus production.
	Meadowsweet	IV	Involves PG-mediated mechanisms.
	Orange essential oil	TU	Carminative action and antispasmodic.
	Peppermint	CT	Relaxation of GIT sphincters.
	Prebiotics	AS	Through stimulation of beneficial bacteria growth, subsequent excretion of antimicrobial compounds inhibiting colonisation of pathogenic bacteria.
	Probiotics	IV, AS, CT	Promotes health-digestive function; eradicates GIT infections and management of GIT disease states.
	Psyllium	CT	Bulking agent, antidiarrhoeal; prevents constipation.
	St John's wort	PH, AS	Inhibits gastric motility.
	St Mary's thistle	AS	Dose dependent.
	Shatavari	IV, AS	Antiemetic, antiulcerogenic, antidiarrhoeal.
	Slippery elm	TU	Demulcent effects.
	Taurine		Conjugation of bile acids.
	Turmeric	IV, AS	Hepatoprotective, cholagogue, hypolipaemic, antispasmodic, wound healing and anti-inflammatory.
	Lavender	TU	Carminative action.
Hepatoprotective			
	Andrographis	AS	Increases liver superoxide dismutase, glutathione peroxidase, glutathione reductase and catalase concentrations, thereby increasing endogenous antioxidant production by the liver; hepatoprotective effect of andrographolide is more potent than that of silymarin.
	Astragalus	AS	Increases liver glutathione levels.
	Baical skullcap	AS	Baicalein, baicalin and wogonin shown to inhibit oxidation and nitration; action may be due to increased metatonin levels; perhaps glutathione sparing mechanism.
	Brahmi	AS	
	Calendula	IV, AS	
	Clove oil	AS	
	Dong quai	AS	Found to exert antioxidant, antiproliferative and pro-apoptotic activities in hepatic stellate cells in vitro.
	Dunaliella salina	AS, CT	May be due to isomeric forms of carotene and other oxygenated carotenoids.
	Fenugreek	IV	
	Garlic	IV, AS	Glutathione-sparing effect on liver.
	Ginger	AS	Effect mediated by antioxidative mechanism.
	Ginseng — Korean	AS	
	Ginseng — Siberian	AS	Protective effect due to water-soluble polysaccharides.
	Globe artichoke	AS	Increases hepatic regeneration, blood flow and antioxidant capacity.
	Grapeseed extract	IV, AS	Inhibits lipid peroxidation and antioxidant activity.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Hawthorn	AS	May be mediated through antioxidant mechanisms.
	Lemon balm	AS	Mediated through antioxidant mechanisms.
	Licorice	IV, AS, CT	Decreases hepatocellular damage in chronic hepatitis B and C; modulates inflammatory mediators and enhances antioxidant mechanisms.
	Meadowsweet	IV, AS	Improved liver function.
	Perilla	AS	Possibly due to antioxidant mechanisms.
	Quercetin	IV, AS	Possibly due to antioxidant mechanisms.
	Rosemary	AS	Attributed to antioxidant mechanisms and enhancing glutathione S-transferase.
	Rhodiola	AS	
	St Mary's thistle	IV, AS, CT	Protective against carbon tetrachloride-induced liver cirrhosis, paracetamol-induced liver peroxidation, and side effects of cyclosporin, phenothiazine, butyrophenone, erythromycin, amitriptyline and nortriptyline, oestradiol, amanita phalloides, tacrine and iron overload.
	SAMe	CT	Significantly increases hepatic glutathione levels.
	Schisandra	IV, AS, CT	Schisandrin B potentiates efficiency of hepatic glutathione antioxidant system, inhibits lipid peroxidation; gomisin A found to inhibit the appearance of histological changes such as degeneration and necrosis of hepatocytes.
	Shatavari	IV	Significantly reduces hepatic enzymes in vitro.
	Stinging nettle	AS	Maintains antioxidant enzyme activity.
	Turmeric	IV, AS	Potent antioxidant; appears to chelate hepatic serum iron in vivo.
	Vitamin B_{12}	AS	
	Withania	AS	Inhibits phase I and activates phase II detoxification enzymes.
Hepatorestorative (i.e. liver repair)			
	Ginseng — Korean	AS	
	St Mary's thistle	AS, CT	Various mechanisms.
	Schisandra	AS	Gomisin A increases ornithine decarboxylase activity, which is important during the early stages of regeneration, and suppresses fibrosis proliferation.
Homocysteine level reduction			
	Folate	CT	
	Garlic	CT	May be through inhibition of CD36 expression and OxLDL uptake by macrophages.
	Vitamin B_6	CT	With B_{12} and folate.
	Vitamin B_{12}	CT	With B_6 and folic acid.
Hypertensive			
	Guarana	PH	Effects due to caffeine content.
Hypoglycaemic/improving blood-sugar control			
	Aloe vera	CT	One clinical study found that blood-sugar levels reduce steadily in people treated with aloe gel, compared with a control group.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Andrographis	IV, AS	Exerts a strong dose-dependent action on insulin production; inhibition of alpha-glucosidase; lowers plasma glucose by enhancing glucose utilisation and may alter glucose absorption.
	Baical skullcap	AS	Mechanisms of action include 5-alpha-aldose inhibition and alpha-glucosidase inhibition.
	Bilberry	AS	Bilberry extracts contain myrtillin, which has been shown to possess hypoglycaemic actions.
	Bitter melon	CT, AS	Hypoglycaemic activity attributed to steroidal saponins, insulin-like peptides and alkaloids. Increases renewal of beta-cells and stimulates insulin secretion.
	Calendula	AS	
	L-Carnitine	CT	Improves insulin secretion, peripheral glucose use and tissue insulin sensitivity.
	Chromium	CT	Blood-glucose regulation; multiple mechanisms.
	Cocoa	CT	
	Cinnamon	CT	
	Cloves	IV	Phenolic compounds may be key constituent responsible.
	Damiana	AS	Experimental model found significant reduction of hyperglycaemic peak, exerting hypoglycaemic effect comparable to tolbutamide.
	Devil's claw	AS	Dose dependent.
	Elder	IV	Increased insulin secretion, muscle glucose uptake, glucose oxidation and glycogenesis in pancreatic beta cells
	Evening primrose oil	AS	
	Fenugreek	AS, CT	Delays glucose absorption and enhances its utilisation; increases tissue insulin sensitivity.
	Garlic	AS, CT	Produces changes in glucose tolerance and insulin secretion.
	Ginger	IV, AS	Hypoglycaemic activity indicated, improves insulin sensitivity.
	Ginseng — Korean	IV, AS, CT	May inhibit glycated haemoglobin.
	Ginseng — Siberian	AS, CT	Increased insulin release, insulin sensitivity and enhanced glucose utilisation.
	Globe artichoke	AS	
	Goji	AS	Polysaccharides and vitamin oxidants responsible for effects.
	Gymnema sylvestre	IV, AS, CT	Multiple mechanisms involved, including reduced intestinal glucose absorption, inhibition of glucose transport and suppression of glucose-mediated release of GIP.
	Hawthorn	AS	
	Myrrh	AS	Increased glucose tolerance.
	Oats	CT	Reduces postprandial glycaemic response.
	Olive leaf	AS	Potentiation of glucose-induced insulin release and increased peripheral uptake of glucose.
	Psyllium	AS, CT	Modulates glycaemic response through various mechanisms.
	Quercetin	AS	Reduction of blood glucose

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Red yeast rice	AS	Acetylcholine release, generating subsequent stimulation of muscarinic M3 receptors in pancreatic cells that effect insulin release.
	Rhodiola	IV, AS	Multiple mechanisms.
	Sage	AS	Decreases serum glucose without affecting insulin release.
	St Mary's thistle	IV	Multiple mechanisms.
	Stinging nettle	AS	Decreases glucose absorption and modifies blood glucose levels.
	Taurine	AS	
	Vitamin B_3	CT	Impairs glucose control in high doses; protects beta cells of the pancreas after onset of type 1 diabetes.
	Vitamin B_6	AS	Reduced diabetic complications.
	Vitamin D	IV, AS	Essential for insulin activation and secretion.
	Withania	IV, AS	Reduced blood glucose and insulin; improved glucose tolerance and insulin sensitivity.
	Zinc		May be mediated via direct and indirect antioxidant role.
Hypotensive — See listing under Antihypertensive			
Immunomodulating			
	Aloe vera	IV, AS	Immune stimulant: antiviral, antitumour and non-specific immunostimulant activity; protective against a variety of fungi and bacteria.
	Andrographis	IV, AS, CT	Immune stimulant: antigen-specific and non-specific immune responses in vivo; immunostimulant activity of the whole extract is greater than the isolated andrographolide constituent. Immunodepressant: andrographolide found to decrease IFN-gamma and IL-2 production; may interfere with T-cell proliferation, cytokine release and maturation of dendritic cells; additionally inhibits T-cell antibody response.
	Arginine		Triggers the release of growth-hormone-stimulating cytotoxic activity of macrophages, natural killer cells, cytotoxic T-cells and neutrophils.
	Astragalus	IV, AS, CT	Immune stimulant: stimulates macrophage activity and enhances antibody responses.
	Baical skullcap	IV, AS, CT	Immune stimulant.
	Beta-carotene	CT	Multiple mechanisms involved.
	Calendula	IV	Stimulates phagocytosis of human granulocytes.
	Chamomile	IV	Immune stimulant.
	Chromium	IV	Chromium has both immunostimulatory and immunosuppressive effects, as shown by its effects on T- and B-lymphocytes, macrophages and cytokine production.
	Colostrum	AS	Immune modulation.
	Dong quai	IV, AS	Enhanced cell-mediated immunity; upregulation of IL-2 and IFN-gamma; suppression of humoral immunity.
	Echinacea	CT	Immune stimulant: activation of polymorphonuclear leucocytes and NK cells and increased T-cells; inhibited NFkappaB, TNF-alpha, NO and cytokines.
	Elder	IV	Increased production of inflammatory cytokines.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Fenugreek	AS	Immune stimulant: enhanced humoral immunity, significant increases in macrophage activity and a stimulatory effect on lymphoproliferation.
	Fish oils		
	Garlic	CT	Immune stimulant.
	Ginger	IV, AS	In vitro and in vivo research suggests that ginger extract exerts some degree of immunomodulatory activity.
	Ginkgo biloba	AS	Immune stimulant attributed to antioxidant properties.
	Ginseng — Korean	IV, AS, CT	Based on the production of cytokines, activation of macrophages, stimulation of bone marrow cells and stimulation of inducible NO synthesis.
	Ginseng — Siberian	IV, AS, CT	Stimulates general non-specific resistance and influences T-lymphocytes, natural killer cells and cytokines.
	Glutamine	AS, CT	Multiple mechanisms.
	Goji	IV	Action includes activation of T cells, B cells and NK cells.
	Goldenseal	IV	
	Honey	AS	Increased humoral immunity in immunocomputent mice.
	Iron	IV, CT	Vital for cell proliferation.
	Licorice	AS	
	Lutein	AS, CT	Modulates cellular and humoral-mediated immune responses.
	Perilla	IV	Stimulates phagocytosis.
	Prebiotics	IV, AS	Through stimulation of beneficial bacteria growth subsequent excretion of antimicrobial compounds inhibiting colonisation of pathogenic bacteria; promoting the production of SCFAs.
	Probiotics	IV, AS, CT	Probiotics bind to intestinal epithelial cells and inhibit the binding of pathogenic bacteria to the gut wall by producing inhibitory substances such as bacteriocins, lactic acid and toxic oxygen metabolites.
	Quercetin	IV, AS	Induction and inhibition of TH1 cytokines.
	Rhodiola	CT	
	Sage	PH, IV	
	Selenium	AS, CT	Confirmed in both animal studies and human trials, immune modulation is in part due to improved activation and proliferation of B-lymphocytes and enhanced T-cell function. Selenium concentrations significantly decrease during stages of acute infection, suggesting either increased utilisation and/or excretion or decreased absorption during this period.
	Shark cartilage	IV	Immune stimulant found to induce TH1 inflammatory cytokines and appears to inhibit TH2 cells.
	Shatavari	IV, AS	Various mechanisms.
	Turmeric	IV, AS	Curcumin has demonstrated both immunostimulant and immunosuppressant activity.
	Vitamin A	AS	Immune-stimulant role includes expression of mucins and keratins, lymphopoiesis, production of antibodies, and the function of neutrophils, natural killer cells, macrophages and T- and B-lymphocytes. Potentiates antibody responses and lymphocyte proliferation in response to antigens. Restores the integrity and function of mucosal surfaces.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Vitamin B_6	CT	Increased T-helper and T-lymphocyte cells in critically ill patients.
	Vitamin B_{12}		Acts as an immunomodulator for cellular immunity.
	Vitamin C	IV, CT	Immune stimulant: favourably modulates lymphocytes and phagocytes, regulates natural killer cells and can influence antibody and cytokine synthesis in certain situations.
	Vitamin D	IV, AS	Promotes differentiation of macrophages and influences cytokine production.
	Vitamin E	CT	Regulates immunocompetence: increases humoral antibody production, resistance to bacterial infections, cell-mediated immunity, the T-lymphocyte response, tumour necrosis factor production and natural killer cell activity.
	Withania	AS	Immunomodulating effects include an increase in white blood cell, platelet and neutrophil counts, increases in interferon-gamma and interleukin-2 levels, and a reduction in tumour necrosis factor level.
	Zinc	AS, CT	Essential for normal development and function of cells mediating non-specific immunity, such as neutrophils and natural killer cells, and affects development of acquired immunity and T-lymphocyte function.
Laxative			
	Aloe vera	AS	Anthraquinones increase intestinal water content, stimulate mucus secretion and induce intestinal peristalsis.
	Dandelion (root)	TU	Mild activity.
	Magnesium	PH	In high doses.
	Oats		Acts as a bulking laxative.
Lipid-lowering			
	Astragalus	CT	In combination with other herbs.
	Baical skullcap	AS	Flavonoid component; mechanism may be due to increased expression of lecithin cholesterol acyltransferase.
	Bilberry	AS	Decreases plasma triglyceride levels.
	Bitter melon	AS	Decreases triglyceride and LDL levels and increases HDL.
	Calcium	CT	Reduced LDL-cholesterol levels by 4.4%, increased HDL-cholesterol levels 4.1% in one study.
	Calendula	AS	
	L-Carnitine	CT	Reduces serum lipoprotein-a levels; changes in other lipid parameters inconsistent.
	Celery	AS	Reduces total serum cholesterol levels.
	Chitosan	CT	Forms complexes with various fats including cholesterol.
	Chromium	CT	Decreases triglyceride levels, total and LDL cholesterol and increases HDL.
	Cinnamon	AS	
	Cocoa	CT	Attributed to cocoa polyphenols and chocolate fatty acids.
	Evening primrose oil	AS	Demonstrated lipid-lowering effects.
	Fenugreek	AS, CT	May be attributed to interaction of fibre and steroidal saponins with bile salts in digestive tract.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Fish oils	CT	Decreases triglyceride levels.
	Flaxseed oil	CT	
	Flaxseeds	CT	
	Garlic	IV, CT	Demonstrated elevation in HDL and reduction in triglyceride levels; mechanisms attributed to inhibition of monoxygenases and HMG-CoA reductase.
	Ginger	CT, AS, EP	May reduce cholesterol and triglyceride levels and development of atherosclerotic lesions.
	Ginseng — Korean	AS, CT	Reduces total cholesterol, triglyceride, LDL and increases HDL.
	Globe artichoke	CT	Reduction in total cholesterol through indirect modulation of hydroxymethylglutaryl CoA reductase activity.
	Goji	AS	Reduces plasma triglyceride and cholesterol levels.
	Goldenseal	CT	Demonstrated for berberine constituent.
	Grapeseed extract	AS, CT	LDL- and triglyceride-lowering activities.
	Green tea	IV	
	Gymnema sylvestre	AS, CT	Serum-cholesterol- and triglyceride-lowering activities.
	Hawthorn	AS, CT	
	Licorice	AS	Reduces total lipids, cholesterol, triglycerides, LDL, VLDL and increases HDL.
	Lycopene	IV, CT	Reduces LDL-cholesterol level.
	Magnesium	CT	Increases molar ratio of apolipoprotein A1:apolipoprotein B; reduces triglyceride levels.
	Myrrh	CT, AS	Guggul or certain constituents within *Commiphora mukul* reduce triglyceride and cholesterol levels.
	Oats	CT	Beta-glucans increase bile acid synthesis and decrease serum cholesterol.
	Olive	CT	Reports inconsistent.
	Perilla	IV, AS	Suppression of HMG-CoA and stimulating acyl-CoA-oxidase.
	Policosanol	AS, CT	Conflicting outcomes. Lowers total cholesterol levels, increases HDL and reduces LDL levels.
	Probiotics	CT	Particular strains may enzymatically deconjugate bile acids and alter the utilisation of cholesterol.
	Psyllium	CT	Alters cholesterol metabolism, increases hepatic cholesterol catabolism and increases faecal bile acid excretion.
	Red clover	CT	Reduce triglycerides and increase HDL.
	Red yeast rice	IV, AS	Significant lipid-lowering activity due to multiple mechanisms.
	St Mary's thistle	AS, CT	Possibly due to inhibition of HMG-CoA.
	Taurine	AS	
	Turmeric	AS, CT	Dose-dependent activity exhibited in vivo; activity may be due to increased cholesterol excretion.
	Vitamin B_3	CT	Reduces total cholesterol, LDL, triglycerides and lipoprotein-a levels and also markedly raises HDL levels.
	Vitamin B_5	IV, AS, CT	Mechanism of action relates to reduced insulin resistance and activation of lipolysis in serum and adipose tissue.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Withania	AS	Decreased lipids, cholesterol, triglycerides and MGH-CoA reductase activity.
Anti-atherogenic			
	Andrographis	AS	Significantly improves atherosclerotic iliac artery stenosis induced by both de-endothelialisation and a high-cholesterol diet.
	Dunaliella salina	AS	Anti-atherogenic.
	Garlic	AS, CT	Reduces atherogenic process.
	Oats	IV	Avenanthramides shown to decrease expression of endothelial pro-inflammatory cytokines.
	Olive	IV, AS	Modifies vascular response, inhibits platelet-activating factor, exerts a suppressive effect on the inflammatory response and protects against carotid atherosclerosis.
	Quercetin	AS	Inhibits key molecules involved in early-stage development of atherosclerosis.
	Selenium	AS	Reduces high-fat diet-induced atherosclerosis.
	Turmeric	IV, AS	Anti-atherogenic.
	Vitamin B_3		Anti-atherogenic.
Male fertility			
	Albizia	AS	Significantly reduces fertility in males; reduces weight of testes, epididymides, seminal vesicle and ventral prostate.
	Astragalus	IV	Stimulates sperm motility.
	L-Carnitine	CT	Increases semen quality, sperm concentration and total and forward sperm motility.
	Ginseng — Korean	CT, AS	Activation of cAMP-responsive element modulator in the testes; improves erectile dysfunction.
	Quercetin	AS	Improves sperm motility, viability and concentration; increases weight of testes, epididymis and vas deferens.
	Selenium	CT, AS	Required for human sperm maturation and sperm motility; positive correlation between selenium levels and sperm density, number, motility and viability. Selenium-dependent antioxidant systems imperative in spermatogenesis.
	Tribulus	IV, AS	Androgenic, producing increase in testosterone and DHEA; protodioscin converts to DHEA; observed pro-erectile effects with protodioscin, due to increased release of NO from the endothelium and nitronergic nerve endings; improves spermatogenesis.
	Vitamin C	CT	Antioxidant mechanism.
	Zinc		Deficiency affects spermatogenesis.
Nephroprotection			
	Ginger	AS	Dose dependent.
	Goldenrod	TU	Believed to stabilise the microarchitecture of the kidneys.
	Lycopene	AS	
	St Mary's thistle	IV, AS	
Neuroprotection			
	Baical skullcap	AS, IV	Action attributed to the flavonoid component; baicalein neuroprotective mechanism attributed to increased dopamine and serotonin and inhibition of oxidative stress.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Brahmi	AS	
	L-Carnitine	AS	
	Cocoa	IV	Flavonoids, epicatechin and catechin protect from amyloid beta-protein-induced neurotoxicity.
	Coenzyme Q10	AS	Antioxidant capacity protects against neuronal damage.
	Creatine	AS, CT	Various theories and possible mechanisms, including antioxidant capacity and mitochondrial stabilising effects.
	Donq quai	IV, CT	Prevented neurotoxicity induced by A-beta-associated oxidative stress in vitro.
	Evening primrose oil	AS	Regulation of thrombotic and inflammatory mediators.
	Fish oils	CT	
	Folate		Improved NO levels in brain and synthesis of neurotransmitters.
	Ginkgo biloba	IV, AS, CT	Mechanisms of action include antioxidant, membrane stabilisation, platelet-activating factor antagonism, mitochondrial activity and anti-amyloid aggregation effect.
	Ginseng — Korean	IV	Dose-dependent neuroprotective activity in vivo and in vitro.
	Ginseng — Siberian	IV, AS	Appears to protect against neuritic atrophy and cell death under amyloid beta plaque and inhibits the release of NO and neuronal apoptosis.
	Goji	IV, AS	Component arabinogalactan-protein appears to have strongest effect.
	Grapeseed extract	IV, AS	Mediated through antioxidant mechanisms.
	Green tea	IV, AS	Epigallocatechin gallate component.
	Licorice	IV, AS	Mediated though antioxidant, anti-inflammatory and modulation of apoptosis pathways.
	Quercetin		Dose dependent.
	Rhodiola	AS	Dose-dependently protects against oxidative stress-induced apoptosis, inhibits NO and restores mitochondrial function.
	St Mary's thistle	IV, AS	Exhibits protective effect on antioxidant defence systems.
	Schisandra	IV, AS	Enhances cerebral antioxidant status and cholinergic function.
	Shatavari	AS	Attributed to antioxidant mechanisms.
	Vitamin B_1 (thiamin)	AS	Deficiency state impairs blood CSF barrier functionality.
	Vitamin B_3	AS	May be mediated through anti-inflammatory and antioxidant mechanisms.
	Vitamin B_6	IV, AS	Activity may be due to GABA inhibition; protects against glutamate-induced neurotoxicity in vivo.
	Vitamin B_{12}	CT	Possibly due to homocysteine reduction.
	Vitamin C		
	Vitamin D		Increased glutathione and reduced NO production, neuroprotective effects.
	Vitamin E		May be mediated via antioxidant activity.
	Withania	IV, AS	May be mediated via antioxidant activity.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
Neurotransmitter effects —See listing under Antidepressant			
Reproductive hormonal effects			
	Black cohosh	IV, AS, CT	Reduces level of luteinising hormone. Oestrogenic activity is controversial.
	Chaste tree	IV, CT	Inhibits prolactin release by selective stimulation of pituitary dopamine D_2 receptors; however, low dose may increase secretion. Stimulates progesterone-receptor expression in vitro; competitive binding to oestrogen receptors alpha and beta in vitro.
	Damiana	IV, AS	Weak oestrogen agonist activity reported; possibly works via progesterone receptors; constituent delta-cadinene is reported to be a testosterone inducer and 1,8-cineole a testosterone hydroxylase inducer.
	Dong quai	IV	Weak oestrogen-receptor-binding activity and weak oestrogen-agonistic activity reported.
	Ginseng — Korean	AS	Gonadotrophin-like action; contains phyto-oestrogens.
	Hops	IV	Significant competitive binding to oestrogen receptors alpha and beta and up-regulation of progesterone receptors.
	Licorice	CT	Conflicting results relating to modulation of testosterone levels; isoflavone component exerts mild oestrogen agonist effect; demonstrated oestrogen-like activities.
	Peppermint	AS	Found to increase FSH and LH and reduce total testosterone.
	Pygeum	IV	Effect upon dihydrotestosterone synthesis; androgen antagonistic activity; oestrogenic and anti-oestrogenic.
	Red clover	IV, AS	Attributed to isoflavone content which demonstrates varying levels of oestrogenic activity.
	Rosemary	AS	Anti-oestrogenic.
	Sage oil	IV	Oestrogenic effects.
	SAMe	CT	Reduces prolactin levels.
	Saw palmetto	AS, CT	Inhibits 5-alpha reductase, preventing the conversion of testosterone to dihydrotestosterone; inhibits binding of DHT and testosterone to androgen receptors and inhibits prolactin.
	Shatavari	AS, CT	Oestrogenic effect on mammary glands and genital organs; galactogogue activity exerted by release of corticoids and prolactin.
	Soy	IV, CT	Selective oestrogen-receptor modulator.
	Tea tree oil	IV	Oestrogenic and anti-androgenic activity.
	Tribulus	IV, AS	Androgenic-producing increase in testosterone and DHEA; protodioscin converts to DHEA; observed pro-erectile effects with protodioscin, due to increased release of NO from the endothelium and nitronergic nerve endings; saponins appear to increase FSH in women, generating an increase in oestradiol.
	Wild yam	IV, AS	Conflicting outcomes; may exert oestrogenic and progesteronal activity or anti-oestrogenic and/or anti-androgenic activity.

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
Thermogenic effects			
	Ginger	AS	
	Green tea	CT	Interaction between catechin polyphenols and caffeine stimulates noradrenaline release and reduces noradrenaline catabolism.
Thyroid modulation			
	Brahmi	AS	Increases T_4 concentration.
	Fenugreek	AS	Reduces conversion of T_4 to T_3, resulting in increased T_4 concentration.
	Iodine	PH	Essential for manufacture of T_4 and T_3.
	Lemon balm		Inhibits binding of thyroid-stimulating hormone to thyroid plasma membranes and extra-thyroidal enzymic T4-5′-deiodination to T_3.
	SAMe	CT	Possible dopaminergic effects.
	Selenium	CT	Required for normal thyroid hormone synthesis, activation and metabolism.
	Withania	AS	Root extract enhances serum T_4 concentration.
Uterine effects			
	Raspberry leaf	AS	Exerts a regulatory action on uterine contractions.
	Shatavari	AS	Inhibits uterine contraction by competitively blocking the effect of oxytocin; action appears mediated through asparagamine, a polycyclic alkaloid.
Visual function			
	Bilberry	ES, AS	Accelerated modulation of retinal enzyme activity, improved microcirculation and antioxidant effect.
	Quercetin	IV	Inhibits lens aldose reductase by 50%.
	Taurine		Required for pre- and postnatal development of visual system.
	Vitamin A		Retinaldehyde essential component of rhodopsin and retinoic acid maintains normal differentiation of cells in the conjunctiva, cornea and other ocular structures.
Wound healing/enhancement			
	Aloe vera	IV, AS, CT	Inhibits thromboxane, which would normally inhibit wound healing in vitro; improves collagen composition and cross-linking; increases proliferation of human keratinocytes and increases epidermal growth factor and fibronectin.
	Calendula	AS, CT	Due to more intensive metabolism of glycoproteins, nucleoproteins and collagen proteins during regeneration of tissues.
	Chamomile	CT	Significantly improved healing and decreased healing time of excision, incision and burns.
	Chickweed	TU	
	Chitosan	PH	Bacteriostatic effect.
	Echinacea	CT	Topically.
	Gentian	AS	Increases stimulation of collagen production and mitotic activity.

Continued

Major actions (known or suspected)	Herb/Nutrient	Evidence	Comments
	Ginseng — Korean	IV, CT	May enhance cell proliferation, epidermal growth factor, fibronectin, keratin, collagenase and angiogenesis.
	Grapeseed extract	IV, AS	Accelerates wound contraction and closure; resveratrol facilitates oxidant-induced vascular endothelial-growth-factor expression in keratinocytes.
	Honey	AS, CT	Topical use, accelerates wound healing, deodorises wounds and assists in debriding.
	Myrrh	TU	
	St John's wort	TU	May be based on anti-inflammatory, analgesic and anti-microbial activities.
	Slippery elm	TU, PH	High mucilage content.
	Turmeric	AS	Healing associated with regulation of the growth factor TGF-beta-1 and iNOS.
	Vitamin B_2	AS	Deficiency lengthens the time to epithelialisation of wounds, slows the rate of wound contraction and reduces the tensile strength of incision wounds.
	Vitamin B_5	IV, AS	Oral and topical administration shown to accelerate closure of wound and increase strength of scar tissue.
	Vitamin C	IV	
	Vitamin E	IV, CT	Assists in repair of abrasions, burns, grazes and skin lesions.
	Zinc	IV, AS, CT	Essential co-factor in wound healing and immune function.

INDEX
